Airplane Registration Number: ________________

Airplane Serial Number: ________________

THIS DOCUMENT MUST BE CARRIED IN THE AIRCRAFT AT ALL TIMES

THIS AIRCRAFT MUST BE OPERATED IN ACCORDANCE WITH THE APPROVED DATA AND LIMITATIONS CONTAINED IN THIS MANUAL AT ALL TIMES.

ANY PERSON FINDING THIS MANUAL IS REQUESTED TO RETURN IT TO JABIRU AIRCRAFT
**Record of Manual Revisions**

This manual is revised as a complete document. All pages must display the same revision number.

# INTRODUCTION

## 0.0 PILOT’S OPERATING HANDBOOK

The POH handbook consists of the following:

### Basic POH

The basic POH provides all the information, procedures and limitations required to operate the aircraft as a Light Sport Aircraft. This basic POH is applicable to all Jabiru J230-D Aircraft.

The operating procedures presented herein are the result of Jabiru Aircraft’s knowledge and experience gained up to the date of issue of this handbook. The handbook may be used for operational purposes only if kept in a fully amended state. It contains all the information considered necessary to safely operate the aircraft.

The operator must be thoroughly familiar with the aircraft and the contents of this handbook before initial operation. Thereafter the handbook should be reviewed periodically to enable the operator to maintain the highest level of familiarity with the aircraft, its controls and recommended operating procedures.

This POH also includes the information required of the Flight Training Supplement: there is no separate FTS for the J230-D.

### Supplements

Self contained supplements are provided in Section 9 of the POH to provide details and procedures associated with the fitment of specified optional and special purpose equipment. Supplements are specific to the particular aircraft S/No. displayed on their title page.

### Amendments

This manual is revised as a complete document. When a new issue of the manual becomes available operators must transfer the aircraft-specific data (such as aircraft weight and balance information and supplements) to the new manual. The old manual must not be used for further operation of the aircraft.

Operators must then familiarise themselves with the new revision of the manual. Those sections of the manual which have been revised are shown with a vertical line in the right margin.

## 0.1 SUPPORTING DOCUMENTATION

The following manuals are required for correct operation & maintenance of the Jabiru J230-D. The current revisions are available free of charge from the Jabiru Aircraft website [www.jabiru.net.au](http://www.jabiru.net.au):

- Pilot’s Operating Handbook
- Engine Maintenance Manual
- Engine Overhaul Manual
In addition, the operator and maintainer must be aware of all current supplemental service information issued by Jabiru Aircraft – again, the latest revisions are available from the Jabiru Aircraft website. These documents include:

- Service Bulletins
- LSA Safety Directives
- Service Letters

Finally, operators and maintainers must be aware of any requirements issued by Airworthiness Authorities and available from their respective web sites:

- Airworthiness Directives issued by the Civil Aviation Safety Authority
- Recreational Airworthiness Notice issued by Recreational Aviation Australia

### 0.2 MANUFACTURER DETAILS

Jabiru Aircraft P/L
PO Box 5186
Bundaberg West,
QLD 4670
Phone: 07 4155 1778
Fax: 07 4155 2669
Email: info@jabiru.net.au

Street Address:
Jabiru Aircraft
Airport Drive, Hinkler Airport
Bundaberg
QLD 4670

### 0.3 STANDARDS LIST

General Airspeed Terminology and Symbols

- **CAS**  *Calibrated Airspeed*: the indicated speed of an aircraft corrected for position and instrument error. Calibrated airspeed is equal to true airspeed in standard atmosphere at sea level.

- **KCAS**: Calibrated Airspeed expressed in knots.

- **IAS**  *Indicated Airspeed*: the speed of an aircraft as shown on the airspeed indicator. IAS values in this manual assume zero instrument error.

- **KIAS** Indicated Airspeed expressed in knots.

- **TAS**  *True Air Speed*: the airspeed of an aircraft relative to the undisturbed air through which it passes.

- **T.O.S.S**  *Take-Off Safety Speed*: the airspeed chosen to ensure that adequate control will exist under all conditions, including turbulence and sudden and complete engine failure during the climb after take-off. It is the speed required at 50 feet.

- **V_a**  *Manoeuvring Speed*: the maximum speed at which application of full available aerodynamic control will not damage or overstress the aircraft.

- **V_{FE}**  *Maximum Flap Extended Speed*: the highest speed permissible with wing flaps in a prescribed extended position.
• **V\textsubscript{NE}** *Never Exceed Speed:* the limiting airspeed that may not be exceeded at any time.

• **V\textsubscript{c}** *Maximum Structural Cruising Speed:* the speed that should not be exceeded except in smooth air and then only with caution.

• **V\textsubscript{s}** *Stalling Speed:* or the minimum steady flight speed at which the aircraft is controllable.

• **V\textsubscript{so}** *Stalling Speed:* or the minimum steady flight speed at which the aircraft is controllable in the landing configuration.

• **V\textsubscript{x}** *Best Angle-of-Climb Speed:* the airspeed which delivers the greatest gain of altitude in the shortest possible horizontal distance.

• **V\textsubscript{y}** *Best Rate-of-Climb Speed:* the airspeed which delivers the greatest gain in altitude in the shortest possible time.

**Meteorological Terminology**

• **OAT** – *Outside Air Temperature* – the outside free air static temperature.

• **Airfield Pressure Height** – The height registered at the surface of an aerodrome by an altimeter with the pressure sub-scale set to 1013 hPa (29.92 inches Hg).

• **Pressure Altitude** – Altitude measured from standard sea-level pressure (1013 hPa/29.92 inches Hg) by a pressure or barometric altimeter corrected for position and instrument error.

• **Indicated Pressure Altitude** – the altitude actually read from an altimeter when the pressure barometric sub-scale has been set to 1013 hPa (29.92 inches Hg).

• **QNH** – The local pressure setting that if set on the subscale of an altimeter will cause the altimeter to indicate local altitude above mean sea level.

• **Wind** – The wind velocities to be used as variables on aircraft performance are to be understood as the headwind or tail wind components of the reported winds.

**Aircraft Performance and Flight Planning Terminology**

• **Climb Gradient** – The ratio of the change in height during a climb, to the horizontal distance travelled.

• **Demonstrated Crosswind Component** – The crosswind component, during take-off and landing, for which adequate control of aircraft was actually demonstrated during certification tests.
Weight and Balance Terminology

- **Datum** – An imaginary vertical plane from which all horizontal distances are measured for balance purposes.
- **Station** – A location along the aircraft fuselage usually given in terms of distance from the reference datum.
- **Arm** – The horizontal distance from the reference datum to the centre of gravity (C of G) of an item.
- **Moment** – The product of the weight of an item multiplied by its arm.
- **Index Unit** – Moment divided by a constant. Used to simplify balance calculations by reducing the number of digits.
- **Centre of Gravity** (C of G) – The point at which an aircraft would balance if suspended. The distance from the C of G to the reference datum can be found by dividing the total moment by the total weight of the aircraft.
- **C of G Arm** – The arm obtained by adding the aircraft’s individual moments and dividing the sum by the total weight.
- **C of G Limits** – The extreme centre of gravity locations within which the aircraft must be operated at a given weight.
- **Useable Fuel** – The quantity of fuel available for flight planning purposes.
- **Unusable Fuel** – The quantity of fuel (determined under adverse fuel flow conditions) that is not available for flight.
- **Empty Weight** – Weight of aircraft with unusable fuel and full oil.
- **Useful Load** – Difference between take-off weight, and basic empty weight.
- **Maximum Take-Off Weight** – Maximum weight approved for take-off.
- **Maximum Landing Weight** – Maximum weight approved for the landing.
- **Header Tank** – Fuel tank plumbed between the wing tanks and the engine. Also known as Collector Tank or Sump Tank.
0.5 USE OF METRIC/IMPERIAL UNITS

This POH uses the metric system as the basic system of measurement. Where common usage or available instrumentation refer to the Imperial/US unit system, both units are quoted. The following conversion factors are presented as a ready reference to the conversion factors that have been used in this manual as well as supplying some others that may be found useful.

1 Pound (lb) = 0.4536 Kilogram (kg)
1 Pound per sq in (psi) = 6.895 Kilopascal (kPa)
1 Inch (in) = 25.4 Millimetres (mm)
1 Foot (ft) = 0.3048 Metre (m)
1 Statute mile = 1.609 Kilometres (km)
1 Nautical mile (NM) = 1.852 Kilometres (km)
1 Millibar (mb) = 1 Hectopascal (hPa)
1 Millibar (mb) = 0.1 Kilopascal (kPa)
1 Imperial gallon = 4.546 Litres (l)
1 US gallon = 3.785 Litres (l)
1 US quart = 0.946 Litre (l)
1 Cubic foot (ft³) = 28.317 Litres (l)
1 Acre = 0.4047 Hectares
1 Degree Fahrenheit (°F) = \[1.8 \times \text{°C}\] + 32
1 Inch Pound (in lb) = 0.113 Newton Metres (Nm)
1 Foot Pound (ft lb) = 1.356 Newton Metres (Nm)

0.6 WARNINGS, CAUTIONS & NOTES

Definitions used in the POH such as WARNING, CAUTION, NOTE are employed in the following context:

 WARNING

Operating procedures, techniques, etc. which if not followed correctly, may result in personal injury or death.

 CAUTION

Operating procedures, techniques, etc. which if not strictly observed, may result in damage to the aircraft or to its installed equipment.

 NOTE

Operating procedures, techniques, etc. which it is considered essential to highlight.
1 GENERAL INFORMATION

1.0 LIGHT SPORT AIRCRAFT NOTIFICATION

There are inherent risks in the participation in recreational aviation aircraft. Operators and passengers of recreational aviation aircraft, by participation, accept the risks inherent in such participation of which the ordinary prudent person is or should be aware. Pilots and passengers have a duty to exercise good judgment and act in a responsible manner while using the aircraft and to obey all oral or written warnings, or both, prior to or during use of the aircraft, or both.

WARNING:

THIS AIRCRAFT WAS MANUFACTURED IN ACCORDANCE WITH LIGHT SPORT AIRCRAFT AIRWORTHINESS STANDARDS AND DOES NOT CONFORM TO STANDARD CATEGORY AIRWORTHINESS REQUIREMENTS.

Jabiru Aircraft Pty Ltd has devoted significant resources and testing to develop the Jabiru J230-D aircraft. The Jabiru J230-D is designed to be operated and maintained only in strict accordance with its supporting documentation – consisting of Pilot’s Operating Handbook, Aircraft Technical Manual (Including Maintenance Manual), Engine Maintenance Manual, Propeller Maintenance Manual, Jabiru Australia Service Bulletins, Service Letters and any other documents produced by Jabiru Aircraft Australia or the appropriate regulatory authorities.

Any variation in procedure or failure to operate or maintain the aircraft according to the supporting documentation may cause damage or harm to the aircraft, its parts, or components and may lead to injury or death. Any such actions may render the aircraft un-airworthy and will void any warranty issued by Jabiru.

Any variation to the aircraft of any kind, including alteration to any component at all, whether replacement, relocation, modification or otherwise which is not strictly in accordance with these documents may lead to dramatic changes in the performance of the aircraft, may cause damage or harm to other parts of the aircraft and may lead to injury or death. Jabiru Aircraft Pty Ltd does not support any modifications to the aircraft, its parts, or components. Any such actions may render the aircraft un-airworthy and will void any warranty issued by Jabiru.

Maintenance cannot be supervised by the manufacturer. Maintenance requires extreme cleanliness, exact parts, precise workmanship and proper consumables. It is your responsibility to ensure absolute attention to detail no matter who may become involved in work on this aircraft. Your safety, your life and your passenger’s lives rely on precise and accurate following of the maintenance documentation for this aircraft.
1.1 ABOUT THE JABIRU J230-D

Jabiru Aircraft have been built in Bundaberg, Australia since the early 1990’s. The original was a small 2 seat aircraft powered by a 2-stroke engine; it had limited range, basic equipment and little room to spare in the cabin. But this aircraft introduced the Jabiru ideal to the world – an aircraft which was light and efficient with good handling, good performance and excellent occupant protection. An aircraft which met all these goals while using modern technology to be cost effective to own and operate and to introduce newcomers to aviation – people who always thought that aviation was beyond their reach. Since the time of those first aircraft, Jabiru Aircraft have evolved dramatically. The current Jabiru models are all far more powerful, spacious and better equipped than their ancestor while still meeting the Jabiru Ideal.

The Jabiru J230-D is the largest factory-complete model offered for sale by Jabiru Australia today. It is a large aircraft, still with 2 seats but with a comfortable, airy cabin. The crew have plenty of space to stretch out while surrounded by windows with panoramic views – the high wing allowing excellent visibility in all directions. The interior of the cabin is neatly upholstered and behind the crew seats is a huge baggage area which can be accessed on the ground via a cargo door for easier loading. In addition to being comfortable, the J230-D is an excellent performer. The aircraft makes a great cross-country machine with cruise speeds of up to two-miles-a-minute (120 Knots, True Airspeed), an endurance of around 5 hours and handling which is smooth and stable. The large, efficient wing easily carries heavy loads and the powerful engine is smooth and quiet so that the crew can fly for hours without fatigue from noise and vibration. At the same time the J230-D is a popular training aircraft - it is easy and fun to fly, forgiving of learner-pilot mistakes and the side-by-side seating makes the instructor’s job easy.

On the ground the J230-D is also an excellent performer – it is a brilliantly simple design which allows maintenance to be carried out quickly and easily to get the aircraft back into the air as soon as possible. The same Jabiru 3300 engine which provides powerful performance in the air is also light, simple, easy to maintain and so quiet that people living near the airport barely hear it. The composite construction allows the aircraft to be both light and very strong – with the J230-D being designed to an ultimate factor of around +8g / -4g. The fibreglass structure won’t rust or corrode, has an almost infinite fatigue life and like all Jabirus, the J230-D has been designed with a very strong cabin structure to provide a safety cell for its crew.

Today’s J230-D is the latest design of an aircraft model which has been a popular choice with owners for over 10 years. The design is thoroughly proven and thoroughly tested – both by Jabiru test pilots and demanding customers all over the world. It can be extensively customised and thanks to the wide range of interior options, instrument systems and other optional extras every Jabiru J230-D is unique. Most importantly, the J230-D still embodies the original Jabiru Ideal and continues to show people who never thought they could have an aircraft of their own that anything is possible.
1.2 OWNER/OPERATOR RESPONSIBILITIES

The following responsibilities for the owner/operator of a LSA listed are prescribed in the ASTM standard F2295:

- Each owner/operator of a LSA shall read and comply with the maintenance and continued airworthiness information and instructions provided by the manufacturer.
- Each owner/operator of a LSA shall be responsible for providing the manufacturer with current contact information where the manufacturer may send the owner/operator supplemental notification bulletins.
- The owner/operator of a LSA shall be responsible for notifying the manufacturer of any safety of flight issue or significant service difficulty upon discovery.
- The owner/operator of a LSA shall be responsible for complying with all manufacturer issued notices of corrective action and for complying with all applicable aviation authority regulations in regard to maintaining the airworthiness of the LSA.
- An owner of a LSA shall ensure that any needed corrective action be completed as specified in a notice, or by the next scheduled annual inspection.
- Should an owner/operator not comply with any mandatory service requirement, the LSA shall be considered not in compliance with applicable ASTM standards and may be subject to regulatory action by the presiding aviation authority.
1.3 J230-D PERFORMANCE & SPECIFICATION SUMMARY

</tbody>
</table>

* Operating Manoeuvring speed at ‘MTOW’ refers to maximum gross weight = 600kg (1323lb).

** Operating Manoeuvring speed at ‘Minimum weight’ is calculated based on typical light empty weight (360kg), a single lightweight occupant (55kg) and 45 minutes reserve fuel (10kg) = 415kg (915lb). Typical operating weight will usually always be much heavier.

Note: Refer to Section 5.3 for conversion to Calibrated Airspeed.

#### 2.0.1 ASI Markings:

- **White Arc**: Flap extended speed range – flapped stall speed to maximum allowable with flaps deployed (42-84 KIAS).
- **Green Arc**: Normal operating Speed range (47-112 KIAS).
- **Yellow Arc**: Caution speed range – Do not exceed this speed except in smooth air and then with caution (112-140 KIAS).
- **Red Line**: Do not exceed this speed in any operation (140 KIAS).

### 2.1 AIRCRAFT SERVICE CEILING

15000 feet ASL.

(Note that RAAus registered aircraft must adhere to the standard 10000 feet ASL limit imposed)

</tbody>
</table>

2.3 FLIGHT OPERATION LIMITATIONS

Manoeuvres in the course of normal flying are approved.

Stalls may be carried out at bank angles of up to 60°.

All aerobatic manoeuvres including spins are prohibited.

Flight Operations are limited to VMC (Visual Meteorological Conditions).

Flight Operations in IMC (Instrument Meteorological Conditions) are prohibited.

2.4 FUEL

Total Capacity: 140L (37 USgal) Total (2 OFF 67.5L Wing Tanks + 5L Header Tank)

Usable Capacity: 135L (35.6 USgal) Useable

Grade: Avgas 100LL, Avgas 100/130 or MOGAS with RON of 95 or higher. See Section 8.5.

Max zero wing fuel weight: Equal to gross weight, 600kg (1323 lb) ($W_{ZWF}$)

2.5 FUEL GAUGES (where equipped)

Fuel pickups are in wing roots. Care must be taken to maintain balanced flight at low fuel levels to ensure that fuel can be drawn from both tanks. If the aircraft is flown for extended periods in an unbalanced condition, it is possible to fully drain one tank while there remains fuel in the other.

2.6 POWERPLANT LIMITATIONS

<table>
<thead>
<tr>

<tr>
<td>Limits For Ground Running</td>
<td>N/A</td>
<td>N/A</td>
<td>180°C (356°F) (Note #2)</td>
<td>100°C (212°F) (Note #2)</td>
</tr>
</tbody>
</table>
Note #1 Time with CHT at between 180°C (356°F) and 200°C (392°F) is not to exceed 5 Minutes

Note #2 If temperature limits are reached, shut the engine down or cool it by pointing the aircraft into wind.

Other limits are as follows:
- Minimum oil pressure at idle: 80 kPa (11 psi)
- Maximum oil pressure at start: 525 kPa (76 psi)

2.7 CROSSWIND

The maximum allowable crosswind velocity is dependent on many factors including:

- Aircraft limitations
- Pilot capability.
- Ground conditions – i.e. turbulence from structures or trees
- Wind state – i.e. steady wind or gusting / thermal conditions.

With average pilot technique, steady, direct crosswinds of up to 14 knots can be handled with safety.

2.8 OTHER CLIMATIC RESTRICTIONS

| Maximum Ambient Operating Temperature | 38°C (100°F) |
| Flight into known icing conditions    | Prohibited   |

2.9 KINDS OF OPERATION

The standard J230-D, as detailed within this POH, is approved for Day VFR Operations only.

An optional package is available to allow the aircraft to conduct Night VFR Operations. Physically this package consists of additional lights and equipment. Aircraft approved for Night VFR Operations must also have such operations approved on their Certificate of Airworthiness and must carry the Jabiru J230-D Night VFR Operations Supplement (Document Number JP-MS-06).

Note

Carrying out Night VFR Operations without a valid, endorsed Pilot Licence, Certificate of Airworthiness, Night VFR Supplement & properly equipped aircraft is illegal. Pilots must ensure the aircraft is appropriate for the intended operations.

2.9.1 JABIRU USA ONLY

Note

Carrying out Night VFR Operations without a valid, endorsed Pilot Licence, Night VFR Operations Supplement & properly equipped aircraft is illegal. Pilots must ensure the aircraft is appropriate for the intended operations.
2.10 POWER GENERATION SYSTEM LIMITATIONS

For aircraft equipped with landing lights (both N-VFR and VFR types) the light requires a large amount of power which can exceed the alternator capacity in some situations. When the engine is turning at approximately 2000 RPM and above the alternator produces sufficient power for all electrical equipment to be run continuously. Below this RPM the alternator may not produce sufficient power and energy must be drawn from the battery if all lights and electrical systems are running.

To reduce the load on the alternator and maintain the battery at peak voltage, Jabiru Aircraft recommend only using the Landing Light for takeoff and landing – turning it off during normal cruise operations and wherever safe while taxiing.

2.11 OTHER LIMITATIONS

- Smoking is prohibited.
- In-cabin noise levels exceed 95db. Hearing protection must be worn.
3 EMERGENCY PROCEDURES

3.0 GENERAL

This section describes the procedures to be adopted in the event of an emergency or abnormal situation occurring in the J230-D aircraft.

The procedures are arranged in the sequence considered to be the most desirable in the majority of cases. Steps should be performed in the order listed unless good reasons for deviation exist.

It should be remembered that all conceivable eventualities cannot be foreseen by the manufacturer. Particular circumstances such as multiple or unanticipated emergencies, adverse weather etc. may require modification to these procedures. A thorough knowledge of the aircraft and its systems is essential to analyse the situation correctly and determine the best course of action in any particular circumstance.

The following basic rules apply to all aircraft emergencies:

1. Maintain Aircraft Control.
2. Analyse the situation before taking appropriate action. Don’t act without thinking.
3. Land as soon as practicable.

3.1 AIRSPEEDS FOR EMERGENCY OPERATIONS

Maximum Glide .............................................. 65 KIAS*
Landing without Engine Power (Flaps Full) ............... 65 KIAS

* - A slightly higher speed may give better distance over the ground if gliding into wind; a slightly slower speed if gliding downwind.
3.2 CARBURETTOR ICING

Carburettor icing occurs when moisture in the air forms ice within the carburettor – typically in the venturi throat and around the throttle butterfly. The ice restricts airflow and prevents the proper function of the carburettor.

Carburettor icing can occur in temperatures between around +30°C (86°F) and -15°C (5°F). Icing most often occurs at cruise, descent or idle power settings, in humid air (including fog, light rain or cloud) and at ambient temperatures between 0°C (32°F) and 20°C (68°F). However, icing can occur at other times and the pilot must be aware of the potential at all times.

Applying carburettor heat is the recommended first corrective measure to be tried in almost any situation for the engine.

Carburettor icing symptoms include:
1. RPM / power reducing for given throttle setting
2. Increased throttle opening required to maintain RPM / power
3. Rough, uneven or surging engine.
4. Engine stoppage

If Carburettor icing is suspected:
1. Throttle ..................................................FULL
2. CARB HEAT ..............................................FULL ON

NOTE
Maintain carburettor heat in ON position for a minimum of 1 minute to allow all ice to melt.

Carburettor heat may be used at any power setting, but will result in a slight power loss. When icing is eliminated, return CARB HEAT to OFF.

DO NOT use carburettor heat for take-offs.

Carburettor heat may be used on the ground except during take-off.

CAUTION
Do not use partial carburettor heat as this may exacerbate ice accretion.
3.3 EMERGENCY PROCEDURES CHECK LISTS

3.3.1 Engine Failures

Engine Failure During Take-off Run
1. Throttle .............................................. CLOSED
2. Brakes ........................................... APPLY
3. Ignition ............................................ OFF
4. Wing Flaps .......................................... UP
5. Master Switch ..................................... OFF
6. Fuel Shutoff Valve ................................ OFF

Engine Failure Immediately After Take-off
1. Airspeed ........................................... 65 KIAS.
2. Ignition ............................................ OFF (As time permits)
3. Fuel Shutoff Valve ................................ OFF (As time permits)
4. Wing Flaps ........................................ FULL RECOMMENDED
5. Master Switch ..................................... OFF
6. Braking ............................................. HEAVY AFTER TOUCHDOWN

Engine Failure During Flight
1. Airspeed ........................................... 65 KIAS*
2. Heading ........................................... TOWARDS CLEAR GROUND
3. Carburettor Heat ................................ ON
4. Fuel Pump .......................................... ON
5. Fuel Shutoff Valve ............................... CONFIRM ON
6. Fuel Quantity ..................................... CHECK
7. Oil ................................................... CHECK TEMP AND PRESSURE
8. Ignition ............................................ CYCLE BOTH ON
9. Throttle ........................................... CHECK LINKAGE OPERATION
10. Airstart ......................................... ATTEMPT IF PROP STOPPED

* - A slightly higher speed may give better distance over the ground if gliding into wind; a slightly slower speed if gliding downwind.
3.3.2 Airstart & Limitations

In the event that the engine is stopped during flight, it may be restarted by application of fuel & ignition, provided that the propeller is still windmilling. The propeller may stop windmilling below 50 KIAS.

The Jabiru engine is a high compression engine & therefore airstarts when the propeller has stopped rotating, without the use of the starter, are unlikely before reaching $V_{NE}$. Therefore, the following procedure addresses only airstarts by use of the starter motor.

**IMPORTANT – NO NOT** depress starter button while propeller is rotating.

1. **Ignition** ................................................................. OFF
2. **Airspeed** .......................................................... REDUCE UNTIL PROPELLER STOPS TURNING.
3. **Establish Glide** ...................................................... 65 KIAS
4. **Fuel** ................................................................. ON
5. **Fuel Pump** ......................................................... ON
6. **Master** ............................................................. ON
7. **Ignition Switches** ................................................ AS NEEDED
8. **Choke** ............................................................... AS NEEDED
9. **Starter Button** .................................................. Depress
10. **Throttle** .......................................................... Open
11. Repeat as necessary, ensuring propeller has stopped before each restart attempt.

**Notes:**
(a) If engine does not restart commence forced landing procedure.
(b) If clear symptoms of a mechanical failure exist, or if the engine has seized due to the loss of oil pressure, do not attempt a restart.
(c) If engine operates with only L or R ignition selected, leave the ignition switch in this position whilst a suitable landing area is selected.
(d) The engine cools quickly with the propeller stopped. Choke may needed to achieve a start.
3.3.3 Forced Landings

Emergency Landing Without Engine Power
1. Airspeed .................................................. 65 KIAS
2. Ignition .................................................. OFF
3. Fuel Shutoff Valve ........................................ OFF
4. Fuel Pump ................................................ OFF
5. Throttle .................................................. CLOSED
6. Wing Flaps ............................................... FULL PRIOR TO TOUCH DOWN
7. Master Switch .......................................... OFF AFTER LOWERING FLAPS
8. Braking .................................................... HEAVY AFTER TOUCH DOWN

Precautionary Landing With Engine Power
1. Airspeed .................................................. 70 KIAS
2. Fuel Pump ................................................ ON
3. Wing Flaps ............................................. TAKE-OFF
4. Selected field ........................................... OVERFLY & INSPECT
5. Wing Flaps ............................................... FULL ON FINAL APPROACH
6. Airspeed .................................................. 65 KIAS
7. Braking .................................................... HEAVY AFTER TOUCH DOWN
8. Ignition .................................................... OFF
9. Fuel Shutoff Valve ...................................... OFF
10. Master Switch .......................................... OFF

Ditching
1. Airspeed .................................................. 65 KIAS
2. Power (if available) ...................................... ESTABLISH 50 ft/min @ 55 KIAS
3. Approach
   High Winds, Heavy Seas ...................... INTO WIND
   Light Winds, Heavy Swells .................. PARALLEL TO SWELLS
4. Wing Flaps ............................................... FULL PRIOR TO TOUCH DOWN
5. Crew ...................................................... BRIEF
6. Doors ..................................................... OPEN
7. Face ....................................................... CUSHION AT TOUCH DOWN
8. Touch Down .............................................. SLOWEST PRACTICAL SPEED
9. Evacuate .................................................. IF REQUIRED BREAK WINDOWS
10. Life Jackets / Life Rafts ............................... INFLATE
11. EPIRB (If Carried) ..................................... ACTIVATE

3.3.4 Fires

Engine Fire During Start

On Ground
1. Ignition .................................................. OFF
2. Fuel Shutoff valve ..................................... OFF
3. Fuel Pump ................................................ OFF
4. Master Switch .......................................... OFF
5. Abandon aircraft ......................................
6. Fire ....................................................... EXTINGUISH

CAUTION
If the fire is in the engine bay do not remove the cowlings. Removing cowls will provide more air to the fire, accelerating combustion.
Engine Fire In Flight

1. Throttle ..................................................... CLOSE
2. Fuel Valve ................................................. OFF
3. Fuel Pump ................................................. OFF
4. Ignition ...................................................... OFF
5. Master Switch ........................................... OFF AFTER FLAPS DEPLOYED
6. Cabin Heat Vent ....................................... CLOSE
7. Cabin Air Vent ............................................ OPEN BOTH
8. Airspeed .................................................... INCREASE UP TO $V_{NE}$* if required to extinguish fire.
9. Forced Landing ......................................... EXECUTE. Refer 3.3.3

* - If necessary to increase airspeed above $V_{FE}$ (to no more than $V_{NE}$) in order to extinguish a fire, the flaps must NOT be lowered.

Electrical Fire In Flight

1. Master Switch ............................................. OFF
2. Ignitions .................................................... ON
3. Electrical Switches ....................................... OFF
4. Extinguisher ............................................... ACTIVATE

If fire goes out:

1. Smoke ....................................................... VENTILATE CABIN (DOORS MAY BE OPENED SLIGHTLY)
2. Precautionary Landing ................................. AS SOON AS PRACTICAL

If fire does not go out:

1. Land ........................................................ EXECUTE IMMEDIATELY

WARNING

With the Master Switch turned off the wing flaps will not deploy.

Cabin Fire

1. Master Switch ............................................. OFF
2. Cabin Heat Vent .......................................... CLOSE
3. Cabin Air Vent ............................................ OPEN BOTH
4. Extinguisher (if fitted) .................................. ACTIVATE
5. Land ........................................................ AS SOON AS PRACTICAL
6. Smoke/Fume Evacuation .............................. VENTILATE CABIN. DOORS MAY BE OPENED SLIGHTLY.

Once fire is extinguished:

1. Power ........................................................ REDUCE
2. Airspeed .................................................... APPROX 80 KIAS
3. Cockpit Door(s) .......................................... CLOSE
4. Power ........................................................ ADJUST to maintain approx 80 KIAS
5. Land ........................................................ AS SOON AS PRACTICAL

NOTE

Doors should only be opened for emergency fume evacuation
3.3.5 Other Emergencies

In some of the cases described below there is more than 1 potential cause for a given situation. For example, if the oil pressure gauge indicates zero, it may be due to a failure of the gauge or sender instead of an actual problem with the engine.

The procedures given below in all cases assume that the indications given are true and correct.

It is important to remain calm and think as clearly as possible. Again: The following basic rules apply to all aircraft emergencies:

1. Maintain Aircraft Control.
2. Analyse the situation before taking appropriate action. Don’t act without thinking.
3. Land as soon as practicable.

Loss of Oil Pressure

1. Airspeed ......................................................... 65 KIAS
2. Power .......................................................... IDLE
3. Precautionary landing .................................. AS SOON AS PRACTICAL

High Oil Pressure

1. RPM ............................................................. REDUCE UNTIL PRESSURE DROPS
2. Precautionary landing .................................. AS SOON AS PRACTICAL

Emergency Descent – Type 1

1. Power .......................................................... IDLE
2. Carburettor Heat ........................................... ON
3. Airspeed .......................................................... 120+ KIAS (less than \( V_{NE} \))
4. Flaps ............................................................. UP

NOTE
This descent gives high vertical speeds but may make controlling the aircraft difficult when passing through narrow holes in clouds etc. Type 1 descents are for clear, smooth air only.

Emergency Descent – Type 2

1. Power .......................................................... IDLE
2. Carburettor Heat ........................................... ON
3. Airspeed ....................................................... 84 KIAS (\( V_{FE} \))
4. Flaps ............................................................. FULL DOWN

NOTE
This type of descent gives high vertical speeds while minimising loads on the aircraft structure and improving controllability around obstacles (such as cloud etc).

S-Turns or Side slips may be used to increase descent rate; see Section 4.10.
Precautionary Descent

1. Power ............................................................... IDLE
2. Carburettor Heat ............................................... ON
3. Airspeed ........................................................... 75 KIAS
4. Flaps ................................................................. UP
5. Bank Angle ......................................................... 30°

NOTE
This descent gives moderate vertical speeds. It allows good airspeed control & is suited to a descent in a confined area (such as a hole in a cloud layer).

Alternator Failure

1. Non-essential electrical equipment ....................... OFF
2. Land ............................................................... AT NEAREST AIRPORT

NOTE
The Jabiru Engine does not require external power to run: the engine will not stop if the aircraft battery runs flat.

Overvoltage

1. Electrical equipment ........................................... ALL ON – MONITOR VOLTAGE
2. RPM ................................................................. REDUCE – MONITOR VOLTAGE
3. Land ............................................................... AS SOON AS PRACTICAL

Inadvertent Spin

Intentional spins are prohibited in this aircraft. Should an inadvertent spin occur, the following recovery procedure should be used:

1. Retard the throttle to idle
2. Centralise ailerons
3. Apply and hold full rudder opposite to the direction of rotation
4. Move stick progressively forward far enough to break stall
5. Hold these control inputs until rotation stops
6. As rotation stops, centralise rudder and make a positive, smooth recovery from the resulting dive

WARNING
If the spin is encountered with flaps extended, DO NOT retract flaps until rotation ceases. Premature flap retraction will delay recovery.

Inadvertent Icing Encounter

1. Carburettor heat ....................................................... ON
2. Altitude ............................................................. REDUCE if safe
3. Aircraft position / heading ................................... TURN BACK
4. Aircraft Performance ........................................... MONITOR

Flight into known icing conditions is prohibited. If icing is inadvertently encountered, change flight level or turn back to a region less conducive to icing. Monitor ice formation on the airframe and its effects on aircraft performance.
Inadvertent Operation in Light Rain

1. RPM ................................................................. REDUCE: 2200 – 2400 RPM
2. Flaps ................................................................. TAKE-OFF (first stage)
3. Carburettor heat ................................................... ON
4. Aircraft Position / heading ..................................... AWAY FROM RAIN

**WARNING**

The J230-D is not designed or approved to fly in heavy rain. The above is included for inadvertent operation in light rain only.

Loss of Primary Instruments

1. Circuit breakers ...................................................... CHECK, RE-SET ONCE ONLY.
2. Master Switch ....................................................... CYCLE OFF-ON
3. Land ..................................................................... AS SOON AS PRACTICAL

**WARNING**

Breakers should only be re-set once. If there is a serious fault in an electrical system repeated re-setting of the breaker can result in an electrical fire.

Landing With a Flat Main Tyre

1. Landing Area ....................................................... SUITABLE
2. Approach ............................................................ NORMAL
3. Wing Flaps ......................................................... FULL DOWN
4. Touchdown ......................................................... GOOD TYRE(S) FIRST, hold aircraft off flat tyre as long as possible with aileron and/or elevator control
5. Ignition .................................................................. OFF
6. Fuel Shutoff Valve ................................................ OFF
7. Master Switch ...................................................... OFF
Loss of Flight Controls

It is a requirement of the design standard that the following section be included in this manual, however such failures are extremely rare. As always, the 3 key rules apply:

1. **Maintain** Aircraft Control.
2. **Analyse** the situation before taking appropriate action. Don't act without thinking.
3. **Land** as soon as practicable.

Primary flight controls failures can potentially be caused by the following:

1. Failure caused when either end of the cable becomes free of its clamp
2. Failure of the cable connecting hardware (bolts, rod ends etc)
3. Failure of the cable itself.
4. Jamming of the controls within the cabin
5. Jamming of the external controls
6. Structural failure of the control
7. Failure of autopilot mechanism

In an emergency the secondary effect of controls may be used to direct the aircraft:

1. The secondary effect of the rudder is to roll the aircraft. Loss of aileron control can be partially addressed through the use of the rudder.
2. The secondary effect of the aileron is to yaw the aircraft. Loss of rudder control can be partially addressed through the use of the ailerons.
3. The trim mechanism is separate to the elevator system and can be used to control the pitch and attitude of the aircraft.
4. In some cases the autopilot mechanism (where equipped) may still function and can be used to control the aircraft.
5. Wing flap position and engine power setting also affect the pitch of the aircraft and can be used to assist in control.

In some cases, shaking a jammed control can free it. However it can also potentially exacerbate the problem. Shaking is therefore not recommended until other troubleshooting techniques have been attempted.

The following steps are recommended:

1. Secondary control..................................................APPLY
2. Cabin end of control cable .....................................CHECK CLAMP & HARDWARE
3. Control mechanism inside cabin ...........................CHECK. Clear any obstructions
4. Control......................................................................SHAKE
5. Brute Force...............................................................APPLY
6. Land ........................................................................AS SOON AS PRACTICAL

**WARNING**

*Where possible have a passenger carry out checks. Complicated or awkward trouble-shooting measures which divert the pilot’s attention should be avoided if possible.*
3.4 AMPLIFIED EMERGENCY PROCEDURES

This section is provided to supply the pilot with additional information concerning emergency procedures in general. Elaboration of the procedures specified in the EMERGENCY PROCEDURES CHECK LISTS as well as the inclusion of some more generalised emergency procedures that can be better covered by a general descriptive procedure rather than a formal check list are included in this section. This will give the pilot a more complete understanding of these procedures.

3.4.1 Fuel Gauges / Low Level warning Light (where equipped)

The J230-D may be fitted with electronic fuel gauges on the instrument panel. In addition, the sender units which drive these gauges are visible in the wing root area and incorporate an analogue needle showing fuel level. While the gauges on the instrument panel are designed so that only extended changes in fuel level are shown, the sender units in the tank show the current level directly and so will change in flight as the fuel sloshes in the tank. These senders can be used as a direct confirmation of the level indicated on the gauges. Note that due to the shape of the wing tank the gauges will read full from when the tanks are full (67 Litres) until the level falls below approximately 50 litres.

The optional low fuel level warning light will illuminate when around 3 litres of fuel remain in the header tank. This will allow the crew around 10 minutes (at cruise power consumption) to attempt to fix the problem with the fuel feed (such as flying out of balance, with the wing containing more fuel higher to encourage fuel flow from it into the header tank) or to locate a suitable place for a precautionary landing. While false indications are possible from this system they are unlikely, and unless the pilot is confident that he has sufficient fuel and that it is reaching the header tank, he should immediately reduce fuel consumption and seek a suitable place to carry out a precautionary landing. Note that this is a separate system from the fuel pressure warning light.

3.4.2 Engine Failure

If an engine failure occurs during the take-off run, the most important action is to stop the aircraft on the remaining runway. The extra items in the checklist will provide additional safety after an engine failure on take-off. If the engine fails shortly after lift off the initial response must be prompt lowering of the nose in order to maintain safe airspeed. In most cases, the landing should be executed straight ahead with only small changes in direction to avoid obstructions. After an engine failure on take-off, altitude and airspeed are seldom sufficient to execute a 180° gliding turn to return to the runway of departure. The checklist procedures assume that adequate time exists to secure the fuel and ignition systems prior to touch down. After an engine failure in flight, the best glide speed should be established as quickly as possible. While gliding toward a suitable landing area, an effort should be made to identify the cause of the failure. If time permits, an engine restart should be attempted. If the engine cannot be restarted a forced landing must be executed.

3.4.3 Forced Landings

If all attempts to restart the engine fail and a forced landing is imminent, a suitable landing area should be selected and the EMERGENCY LANDING WITHOUT ENGINE POWER checklist should be completed if at all possible.
3.4.4 Ditching
The aircraft has not been flight tested in actual ditchings, therefore the recommended procedure is based entirely on the best judgement of the manufacturer.

If available, life jackets should be donned but not inflated until after evacuating the aircraft. Inflating the life jackets prematurely increases the risk of damage to them exiting the aircraft. Additionally their bulkiness adds to the difficulty of evacuating the aircraft.

Plan the approach into wind if the winds are high and the seas are heavy. With heavy swells and light winds, land parallel to the swell. If possible maintain a constant descent rate of approximately 50 ft/min almost until touchdown but reducing speed to the minimum practical immediately prior to touchdown. Water pressure may hold the doors closed, so the crew should be prepared to break out windows if necessary to equalise pressure and allow egress. An orderly evacuation of the aircraft should then be conducted.

3.4.5 Fires
Although engine fires are extremely rare in flight, the checklist procedures should be followed if one is encountered. After completion of this procedure, execute a forced landing. Do not attempt to restart the engine after an engine fire.

The initial indication of an electrical fire is usually the smell of burning insulation. Turning off the Master Switch should result in the elimination of the cause of this type of fire, but it will also result in the loss of all power to instruments & controls.

3.4.6 Rough Engine/Loss of Power

1. USE OF POWER Continuous RPM up to 3300 is allowed in normal operations. In emergencies engine RPM in excess of 3300 may be used, but this will only be available at speeds above about 100 KIAS.

2. SPARK PLUG FOULING Slight engine roughness in flight may be caused by one or more spark plugs becoming fouled by carbon or lead deposits. This may be verified by selecting each ignition switches momentarily to OFF. An obvious power loss in single ignition operation is evidence of spark plug or ignition system trouble. Assuming that the spark plugs are the more likely cause, applying full throttle may clear the plug fouling. If this does not solve the engine problem, plan to land at the nearest practical airfield to have the situation investigated.

3. IGNITION MALFUNCTION A sudden engine roughness or misfiring is usually evidence of carburettor icing or ignition system problems. In the case of ignition system trouble, switching each ignition switch off in turn should identify which system is malfunctioning. Different power settings may alleviate the problem. If not, plan to land at the nearest practical airfield to have the situation investigated.

4. CARBURETTOR ICING Rough running and loss of power may be caused by carburettor icing. This is most likely in conditions of high humidity and at low power settings. If not corrected, ice build up in the carburettor throat will cause complete power loss. If carburettor icing is suspected, immediately apply full carburettor heat until normal engine operation is restored, and the heat can be selected OFF. Carburettor heat should only be selected ON or OFF, as partial heat application may
exacerbate ice build-up. The aircraft can be safely operated with carburettor heat applied for indefinite periods, but there will be a slight power loss. Hence, carburettor heat should not be used when full power is required; e.g. for take-off.

5. **LOW OIL PRESSURE** If low oil pressure is accompanied by normal oil temperature, there is a possibility that the oil pressure gauge or the relief valve is malfunctioning, and an immediate precautionary landing is not warranted. A landing at the closest practical airfield is advisable however so that the source of the trouble can be investigated. If a total loss of oil pressure is accompanied by a rise in oil temperature, an engine failure is probably imminent. Reduce engine power immediately and select a suitable forced landing area. Use only the minimum power required to reach the desired touch down point.

### 3.4.7 Electrical Systems Malfunctions

The electrical system is straightforward but to obtain the necessary degree of reliability and redundancy the system must be operated correctly. Normal operation is with the Master Switch in the ON position. Should the need to shed electrical loads arise the pilot should use their discretion to turn off all non-essential electrical equipment. More severe electrical system failures, such as those resulting in fire, require the Master Switch to be switched off. In addition to the general guide above specific failures may be dealt with as follows.

1. **INSUFFICIENT RATE OF CHARGE** If the “CHG FAIL” light illuminates in flight, minimal or no electrical power is being supplied by the alternator. If the battery charge drops sufficiently electrical systems will fail. While the Jabiru engine does not require external power while running, devices such as radios, transponders, GPS units, and intercoms will eventually drain the battery. If this light illuminates, consideration should be given to landing at the nearest practical airfield, though – provided the eventual total loss of electrical services will not affect the safety of flight – the flight may continue.

2. **CIRCUIT BREAKERS** Failure of an individual circuit will, in most circumstances, result in opening of the relevant circuit/switch breaker. To ensure a permanent fault exists in the circuit the breaker should be reset once. If the breaker again pops the circuit is faulty and the flight should be continued without that service.
4 NORMAL PROCEDURES

4.0 GENERAL

This section describes the procedures to be adopted for normal operations of the J230-D aircraft.

The procedures are arranged in the sequence considered to be the most desirable and therefore steps should be performed in the order listed unless good reasons for a deviation exist. The lists below include checks for all optional equipment, so checks that do not apply to this aircraft may be skipped.

4.1 SPEEDS FOR NORMAL OPERATION

Unless otherwise noted, the following speeds are based on a maximum weight of 600 kg (1323lb) and may be used for any lesser weight.

Note that generally the best rate of climb speed & best angle of climb speed are not used during normal operations. This is because they place a higher degree of stress on the engine & leaves a relatively small margin to cope with gusts, turbulence etc. The higher climb speeds below are recommended for all cases where a slight decrease in the aircraft's climb rate is acceptable. In cases where maximum climb performance is required then \( V_X \) or \( V_Y \) must be used.

Take-Off:
- T.O.S.S. (Speed @ 50 ft)..............................65 KIAS
- Normal Climb Out .........................................80 KIAS (Take Off Flap)

Climb, Flaps Up:
- Initial (scheduled climb) ..............................80 KIAS
- En-route.........................................................90-100 KIAS

Landing Approach:
- \( V_{REF} \) (Speed @ 50 ft) ..............................65 KIAS
- Baulked Landing...........................................65 KIAS Initially

Maximum Recommended in Turbulence:
- All Weights ..................................................112 KIAS

4.2 BEST ANGLE OF CLIMB SPEED

\( V_X \) – Best Angle of Climb Speed ...............58 KIAS

4.3 BEST RATE OF CLIMB SPEED

\( V_Y \) – Best Rate of Climb Speed .......................78 KIAS
4.4 PREFLIGHT INSPECTION

Before flight, a careful visual inspection is to be carried out to ensure that the aircraft and its systems are serviceable. Aircraft must be placed in a clear area of level ground to carry out the inspection.

CAUTION

Do not carry out inspection while distracted – i.e. due to onlookers etc

The following Figure is to be used in conjunction with the pre-flight inspection checklist:

![Figure 4-1. Pre-flight Inspection](image)

4.4.1 Remove Covers / Release Aircraft

A. Remove covers from engine exhaust, inlet, cowl openings etc.
B. Remove left wing tie-down
C. Remove left wing fuel vent cover
D. Remove cover from static source
E. Remove tail tie-down
F. Remove right wing fuel vent cover
G. Remove right wing tie-down
H. Remove nose leg tie down (where used)
J. Lower Flaps
4.4.2 Pre-flight Inspections

1. Engine

   Engine Oil…………………………………….. CHECK using oil filler door.
   Pull Through……………………………….. CARRY OUT as detailed below.

   Before the first flight of the day the engine must be “pulled through” by hand. This is the process
   of turning the propeller by hand. The compression of each cylinder in turn will be felt a resistance
   as the propeller is turned. The engine should be rotated for a count of at least 8 compressions.

   Master Switch……………………………..OFF
   Ignitions……………………………………OFF
   Throttle……………………………………..Closed
   Propeller…………………………………….TURN by hand & observe engine for odd
                                              noises or heavy movements. Check for
                                              regular compression.

   CAUTION:
   Prior to pulling through the propeller by hand, the engine must be cold, both ignition circuits & the
   Master Switch must be switched OFF, the brakes applied & throttle closed.

   WARNING
   A hot engine may fire with the ignition/s switched OFF. DO NOT pull through a hot engine.

   CAUTION
   Several causes of irregular compression – such as leaking valves – can lead to extensive engine
   damage if not addressed. The Jabiru Engine Maintenance Manual provides additional details.

2. Propeller

   Propeller…………………………………….. CHECK for damage & security
   Spinner…………………………………………CHECK for damage, wear, hardware.

3. Nose Area General

   Cowling…………………………………….. CHECK Security, rubbing on engine.
   Leaks…………………………………………CHECK cowl outlets for leakage of oil etc.
   Nose Wheel……………………………….. CHECK condition & pressure
   Nose Leg…………………………………….CHECK as given below.

   Squat in front of the aircraft and push the nose from side to side, up & down by pressing on the
   propeller. Some movement and flex in the nose leg is normal however excess movement &
   noises indicate damage or wear which must be corrected.

4. Left Wing

   Leading Edge………………………………CHECK for dents, cracks, hangar rash
   Tip………………………………………………..CHECK for dents, cracks, hangar rash
   Tip………………………………………………..SHAKE fwd-aft, up-dn: check for free-play*
   Aileron…………………………………………CHECK Security & Full & Free Movement
   Aileron cable clamp………………………….CHECK secure through inspection window
   Control Hinges……………………………..CHECK secure & pin retainers in place.
   Flap ……………………………………………..CHECK Security
   Left fuel cap………………………………….CHECK security
   Landing Light………………………………..CHECK security.
   Wingtip Lights……………………………..CHECK security
   Stall Warning Opening……………………..CHECK clear, tab not damaged.
Control rods & cables ..................................CHECK Security. Check rod ends for freedom of rotation & excess movement.

* - Holding the wingtip, push the tip up & down, forwards & backwards. If a wing / strut attachment is degrading, free-play will be felt.

5. **Left Undercarriage**
   - Mount bolts............................................CHECK SECURE*
   - Tyre..................................................CHECK CONDITION / INFLATION
   - Brakes...............................................CHECK condition

* - Lock the hand brake on, then pull the aircraft forwards. Some flexing of the undercarriage legs is normal, but there should be no movement of the top of the leg relative to the fuselage.

6. **Static Source**
   - Static Source............................................CHECK for blockage & straightness

7. **Empennage**
   - Control surfaces......................................CHECK Security & Full & Free Movement
   - Rudder, Elevator & Trim Cables ..................CHECK Security & Full & Free Movement
   - Control Hinges.......................................CHECK secure & pin retainers in place.
   - Trim / elevator mechanism .......................CHECK through inspection hole in ventral fin
   - Lights..................................................CHECK Security.

8. **Right Wing**
   - Leading Edge.........................................CHECK for dents, cracks, hangar rash
   - Tip......................................................CHECK for dents, cracks, hangar rash
   - Tip.....................................................SHAKE fwd-att, up-dn: check for free-play*
   - Aileron...............................................CHECK Security & Full & Free Movement
   - Aileron cable clamp..................................CHECK secure through inspection window
   - Control Hinges.......................................CHECK secure & pin retainers in place.
   - Flap....................................................CHECK Security
   - Right fuel cap........................................CHECK security
   - Landing Light........................................CHECK security.
   - Wingtip Lights.......................................CHECK security
   - Control rods & cables..............................CHECK Security. Check rod ends for freedom of rotation & excess movement.
   - Pitot Tube.............................................CHECK for blockage.
   - AOA / Pitot Head (where equipped).............CHECK. All openings open / unobstructed
   - AOA / Pitot Head (where equipped).............CHECK. Installation secure

* - Holding the wingtip, push the tip up & down, forwards & backwards. If a wing / strut attachment is degrading, free-play will be felt.

9. **Right Undercarriage**
   - Mount bolts.........................................CHECK SECURE*
   - Tyre..................................................CHECK CONDITION / INFLATION
   - Brakes...............................................CHECK condition

* - Lock the hand brake on, then pull the aircraft forwards. Some flexing of the undercarriage legs is normal, but there should be no movement of the top of the leg relative to the fuselage.
10. **Fuel Quick Drains**
Test fuel at each drain ..................... CHECK for contamination

11. **Stand Back Inspection**
Stand back from the aircraft & check for anything “out of place”. i.e: assuming the aircraft is on flat ground if the wingtips are not level it can indicate damage to the undercarriage.

   Turn all external lights on................... CHECK for correct function
   Wings level .................................. CHECK.
   All hatches & fairings secure .............. CHECK
   Nothing out of place .......................... CHECK

12. **Cockpit**
   Quantity in both fuel tanks .................. CHECK SUFFICIENT
   Ignition Switches ............................ OFF
   Control lock (if fitted) ...................... REMOVE
   Fuel valve .................................... ON
   Master switch ................................ ON
   Alternator Warning Light ..................... CONFIRM ON Before Start
   Wing flaps ..................................... RETRACT
   Master Switch ................................. OFF
   Control cables & fasteners ................... CHECK
   Rudder & nose wheel steerage linkage ....... CHECK
   Rudder centring springs ..................... CHECK
   Controls (all) .................................. CHECK full travel, free movement.
   Harnesses & Seats ............................ CHECK CONDITION
   Windshield ..................................... CLEANLINESS
   Cockpit area .................................. GENERAL CONDITION
   Loose objects .................................. SECURE
   Cockpit Doors/Latches ....................... CONDITION & OPERATION
   POH ........................................... AVAILABLE
   Carbon monoxide detector .................... CHECK EXPIRY

Note: for aircraft not fitted with an ‘Alternator Warning Light’, the EIS engine monitor is used to give an indication of voltage.

**Instruments**
   Heading indicator ......................... Check
   Engine Instruments ......................... Confirm normal operation

**Interior / Map / Instrument Lights**
   Lights ................................................. Check operation
4.5 NORMAL PROCEDURES CHECK LISTS

4.5.1 Before Starting Engine

- Pre flight Inspection .................. COMPLETED
- Passenger Briefing .................. COMPLETED
- Harnesses ............................ SECURE
- Brakes .................................. ON/PARK
- Avionics (except EMS) .............. OFF
- EMS ..................................... ON
- Circuit Breakers ...................... IN

4.5.2 Starting Engine - Cold

- Master Switch ......................... ON
- Fuel Shutoff Valve ..................... ON
- Carburettor Heat ....................... OFF
- Choke .................................. HOLD FULLY ON*
- Throttle ................................ CLOSED
- Fuel Pump .............................. ON
- Ignition switches ...................... ON
- Starter .................................. ENGAGE when engine fires RELEASE**
- Oil Pressure .......................... CHECK (pressure to be indicated within 10 secs)
- Choke .................................. Closed
- Throttle ................................. 900 – 1000 RPM
- Alternator Warning Light .......... CHECK OFF
- Avionics ............................... ON

* - If the engine is hot, proceed as for cold engine, but do not use choke.
** - If the engine is turned by the starter at less than 300 RPM it will not start.

Note: for aircraft not fitted with an ‘Alternator Warning Light’, the EIS engine monitor is used to give an indication of voltage.

4.5.3 Taxiing

- Power ................................... 1000-1200rpm
- Speed ................................... FAST WALKING PACE MAXIMUM
- Strobe ................................... ON
- Landing Lights ......................... OFF UNTIL ENTERING RUNWAY
- Position ............................... STAY RIGHT on taxiways
- Carburettor heat ....................... AS REQUIRED
- Brakes .................................. AS REQUIRED. Do not apply continuously.

If required, brakes should be applied periodically: allow the speed to build up to a fast walking pace then apply brakes to reduce to a slow walking pace. Release the brakes and allow the speed to gradually build up again. This allows the brakes time to cool down between applications & minimises wear.
4.6 Before Take-Off

4.6.1 Ground Check & Run Up

Warm Up ................................................. 1000-1200 RPM avoid prolonged idle at low RPM
Ignition Check .............................................. 2000 RPM Both-L-Both-R-Both. Max drop 100RPM
Carburettor heat ........................................... 2000 RPM – ON – slight drop in RPM
Carburettor heat ........................................... 2000 RPM – OFF – RPM restored
Full power Check .......................................... 2850 RPM +/- 150 RPM
Idle Check ...................................................... 700 – 900 RPM – NO STALL.
Trim .......................................................... SET – Neutral
Avionics ...................................................... Check (pitch, heading, etc)

4.6.2 Pre Take-Off

Master Switch ............................................... ON
Ignition switches ......................................... BOTH ON
Fuel Shutoff Valve ........................................... ON
Fuel Quantity .................................................. CHECK sufficient for task
Fuel Pump ......................................................... ON
Flaps ............................................................. TAKE OFF (first stage)
Instruments ...................................................... SET AND CHECK ALL
Switches ......................................................... SELECTED as required
Circuit Breakers .............................................. CHECK
Controls ........................................................ FULL & FREE TRAVEL, CORRECT SENSE
Elevator trim .................................................. SET CENTRAL
Hatches ......................................................... CLOSED & LOCKED
Harnesses ...................................................... SECURE all seat belts correctly fastened and adjusted
Oil temperature ........................................... ABOVE 40°C (104°F).

4.7 Take-Off, Flight & Landing

4.7.1 Take-Off

Carburettor heat ............................................. OFF
Throttle .......................................................... FULL OPEN
Elevator Control .............................................. NEUTRAL
Directional Control .......................................... NOSEWHEEL STEERING & RUDDER
Rotate .......................................................... 30 – 40 KIAS raise nosewheel off ground*
Take Off Safety Speed .................................. 65 KIAS
Elevator trim .................................................. AS REQUIRED
Accelerate to Normal Climb Speed ................. 80 KIAS or,
Speed to clear close obstacle ....................... 58 KIAS ($V_s$) or,
Speed for best time to altitude ..................... 78 KIAS ($V_y$)
Flaps ............................................................. UP once at Climb speed & above 200’ AGL
En-route Climb Speed .................................. 90 – 100 KIAS
Fuel Pump ..................................................... OFF at top of climb.
Power .......................................................... SET as required.

* - In cross winds do not rotate until 45 KIAS for better directional control.
4.7.2 Cruise
75% Power........................................2800 RPM

4.7.3 Descent
Power.............................................As required
Carburettor heat.................................As required

4.7.4 Before Landing (and flight below 1000ft AGL)
Brakes..............................................OFF
Harnesses..........................................SECURE
Fuel Pump......................................ON

4.7.5 Approach
Speed..............................................65 KIAS
Wing Flaps.......................................1 STAGE BASE, 2nd STAGE ON FINAL
Trim..................................................AS REQUIRED
Carburettor Heat...............................ON

4.7.6 Normal Landing
Airspeed @ 50ft..................................65 KIAS
Wing Flaps........................................FULL
Directional Control................................RUDDER & NOSEWHEEL STEERING
Power .............................................AS REQUIRED
Touchdown.........................................MAINS FIRST. Hold nose wheel off*.
Braking............................................AS REQUIRED

* - In cross winds lower nose wheel earlier for better directional control.

NOTE
If the aircraft is contaminated by build up of insects or other debris, increase approach speed by 3 – 5 KIAS

4.7.7 After Landing/Securing
Wing Flaps.........................................UP
Fuel Pump.........................................OFF
Fuel Shutoff Valve..............................remains ON
Parking Brake....................................ON/AS REQUIRED
Avionics..........................................OFF
Ignition...........................................OFF
Master Switch...................................OFF
Controls..........................................SECURE
4.8 Special Procedures

4.8.1 Baulked Landing

Power ................................................. FULL THROTTLE
Carburettor heat ............................... COLD
Control yaw to left ............................ RUDDER
Control pitch up .............................. ELEVATOR
Airspeed ............................................ ESTABLISH NORMAL CLIMB SPEED
Wing Flaps ....................................... RETRACT SLOWLY

NOTE
Full power, full flap go-around will produce an initially strong yaw to the left and nose pitch up. These effects must be anticipated & controlled using the rudder and elevator respectively.

4.9 AMPLIFIED PROCEDURES

This section is provided to supply the pilot with additional information concerning normal procedures in general. Elaboration of the procedures specified in the NORMAL PROCEDURES CHECK LISTS as well as the inclusion of some more generalised procedures that can be better covered by a general descriptive procedure rather than a formal check list are included in this section. This will give the pilot a more complete understanding of these procedures.

4.9.1 Preflight Inspection

The Preflight inspection as covered by the PREFLIGHT INSPECTION CHECKLIST is recommended prior to the first flight of the day. Inspection procedures for subsequent flights can be abbreviated provided essential items such as fuel and oil quantities, security of fuel and oil filler caps are satisfactory. After refuelling fuel samples must be taken from all drain points, three in total, one in each of the two wing fuel tanks and one under the fuselage.

Aircraft operated from rough strips, especially at high altitudes, are subject to abnormal undercarriage abuse. Frequent checks of all undercarriage components, tyres and brakes is warranted in these situations.

4.9.2 Electric Fuel Gauges (where equipped):

The fuel gauges used in the J230-D use a sender unit which has a built-in analogue needle indicator for fuel level. These senders are located in the wing roots and are visible to the crew. These units may be used to confirm the fuel level being displayed by the indicators fitted to the instrument panel. Note that due to the shape of the wing tanks, the gauges will read full from when the tank is full until it’s level has dropped below around 50 litres. This must be taken into account by manually checking fuel quantity (dipping the tanks) before a long flight.

4.9.3 Starting Engine

The Jabiru 3300 engine is fitted with a dual electronic ignition system. The engine will not start below 300 RPM, which precludes the option of hand swinging or “propping” an engine when there is insufficient charge available in the aircraft battery for a normal start. Starting using an external power source involves removing the upper engine cowl, attaching jumper leads to the battery terminals and proceeding with the normal start sequence.

WARNING
When the engine is started, and battery charge restored, shut down before re-fitting the engine cowl

After starting, oil pressure should start to rise within 10 seconds. If it does not rise within this time stop the engine and investigate the cause.

4.9.4 Taxiing

Positive control is available to the pilot when taxiing the J230 due to the direct linkage type nosewheel steering. Care should be exercised in strong winds, particularly in quartering tail wind conditions. As with any high wing configuration aircraft, appropriate elevator and aileron control positions are essential during taxiing operations particularly during strong tail wind conditions.

Taxiing over loose gravel or stones should be done at low engine RPM to minimise propeller damage.

4.9.5 Engine Management – Ground Running

The 3300 engine fitted to the J230-D is cooled by air flowing over the engine and oil cooler. During ground running care must be taken to ensure that there is adequate airflow and that safe engine temperatures are maintained. The guidelines presented below will assist in controlling temperatures.

- Minimise ground running times – especially in hot weather.
- Carry out as many checks as possible before starting the engine.
- Always carry out engine run-up tests with the aircraft pointing into wind.
- In hot weather, after performing run-up checks, leave the aircraft pointing into wind and idling at 1200rpm for 30 seconds to aid cooling.
- If the aircraft is required to wait – such as for runway clearance – temperatures must be monitored, and if they approach ground running limits (listed in Section 2 of this flight manual & displayed as yellow markings on engine gauges) the aircraft must be turned into wind or shut down to prevent any further temperature increase.
- Wind must be coming from within approximately 45° of the aircraft heading to be effective in aiding engine cooling.
- If there is no wind or low wind the engine must be shut down if ground-running temperature limits are reached.

4.9.6 Warm Up

Most of the warm up will have occurred during taxiing and whilst conducting the Before Take-Off checks. The engine is warm enough for take-off when the cylinder head and oil temperatures are in the green arcs.

Ignition System Check

The magneto check should be made at 2000 RPM as indicated by the tachometer with the carburettor heat set to COLD. Select the LEFT ignition OFF and note the RPM drop, return to BOTH until the engine regains speed. Select RIGHT ignition OFF and note the RPM drop, return to BOTH. Drop in RPM should not exceed 100 RPM. Do not operate on a single ignition

2 \(^{30^\circ}C\) and above
source for an extended period; a few seconds is usually sufficient to check RPM drop and will minimise spark plug fouling.

4.9.7 Take-Off

Power Check

Full throttle runups over loose gravel are especially harmful to the propeller and should be avoided. When take-offs must be made from a gravel surface, it is very important that the throttle be advanced slowly and a rolling start take-off technique be used to minimise propeller damage.

It is important to check full throttle engine performance early in the take-off run. Any sign of rough engine operation or sluggish acceleration is good cause for discontinuing the take-off and conducting a full power runup to confirm normal engine operation prior to the next take-off attempt.

Wing Flap and Power Settings

Normal take-offs are accomplished at full throttle, and TAKE-OFF flap selected. The flaps should not be retracted until a safe height is achieved and all obstacles have been cleared. Take-offs may be made with flaps up but this will increase the take-off distance and will result in a more pronounced nose up attitude at lift off.

4.9.8 Climb

Enroute climb

Enroute climbs are performed with flaps up, full throttle, and at speeds 5 to 10 knots higher than the best rate of climb speed. This provides better engine cooling with little loss of climb performance.

4.9.9 Cruise

The power setting and cruising altitude are the two major factors that will affect the cruising speed and range of the J230. Other influencing factors include the weight and loading, temperature and equipment installed in a given aircraft. The maximum power setting normally used for cruise is 75% of the engine’s rated power. Power settings below this will result in increased range and endurance corresponding with the reduced fuel consumption. At a power setting of 45% the J1230 is capable of attaining an endurance of close to 10 hours, for a range of over 900 nautical miles. For efficient and economical operation as well as to achieve maximum engine service life the engine must always be operated in accordance with the procedures and specifications set out in the engine manufacturer’s operator's manual.

4.9.10 Stalls

In any attitude or under any loading condition there is no natural stall warning. An artificial stall warning horn is set to activate 5 to 10 KIAS above the stall speed in any configuration. All controls are effective up to and completely through the stall and there is no noticeable tendency to enter a spin after the stall.
4.9.11 Approach and Landing

Landings are normally conducted with full flaps. The landing approach is conventional. Care must be taken to ensure airspeed is accurately maintained during the final landing approach. Timely and appropriate use of power should be exercised to maintain the desired flight path and airspeed. Excessively high approach speeds will result in prolonged floating and increased landing distance. Normally the throttle should be fully closed during the 'flare' to reduce the tendency to float and prolong the touchdown. Touchdown should occur on the main wheels initially, followed by the nose gear which should be held clear of the ground during the initial ground roll. Positive braking may then be applied depending on requirements and circumstances. For maximum braking effectiveness the wing flaps should be retracted and back pressure applied to the control column.

4.9.12 Cross Wind Landing

The J230-D has been approved for operations in crosswinds of up to 14 Knots.

When landing in a strong cross wind use a wing low, crab, or a combination method of drift correction. Avoid a prolonged hold off by allowing the aircraft to settle onto the runway in a slightly nose high and wing low attitude, touching down on the into wind mainwheel first followed by the other mainwheel and then the nose gear in quick succession. In strong and/or gusty wind conditions it may be desirable to make the final approach at a slightly higher than normal airspeed with partial or no flap selected.

4.9.13 Baulked Landing

In a baulked landing (go-around), the wing flaps should be retracted to take-off immediately after full power has been applied. Upon reaching a safe airspeed, the flaps should be smoothly retracted to the full up position and a normal climb established.

4.9.14 Flight Over Water

When life preservers and rafts are required, crew life preservers should be worn at all times. Life rafts can be stowed in the baggage compartment.
4.10 Advanced Procedures

The following procedures are advanced techniques designed for special circumstances. To carry them out successfully the pilot must be well trained and experienced in the particular aircraft being used. Before attempting them the pilot must realistically assess the circumstances and their skills.

**WARNING**
The following procedures are used in less than optimal conditions. They are inherently less safe than normal procedures. The operator attempts them at their own risk.

4.10.1 Short Field Take-Off

</tbody>
</table>

**NOTE**
Short field take-offs are potentially high risk manoeuvres. Reducing rotation and climb speeds lower the aircraft’s safety margins, especially in a cross wind, wind gust or if the engine fails.

Where possible, they should only be attempted in good conditions. If students are being taught short field take-offs the weather conditions must be appropriate and a long runway used.

**WARNING**
If high power is applied when the propeller is over loose gravel, grass etc propeller damage will result.

**WARNING**
It is possible to over-rotate the aircraft in ground effect to a dangerously nose-high pitch, resulting in a stall once clear of ground effect. Allow pitch angle & airspeed to stabilise out of ground effect before applying aggressive pitch inputs.
4.10.2 Short Field Landing

Approach..............................................FLAT. Aim for wheels to touch as near to the
target point as possible. Approach under power.

Power................................................APPROX 1500 RPM
Airspeed..........................................55 KIAS
Touch-down.....................................AT TARGET POINT. Wheel brakes are the best way to slow the aircraft. Touching
down positively and slightly fast then braking heavily will give shortest landing distances.

Power..............................................IDLE
Brakes.............................................HEAVY. DO NOT LOCK WHEELS.

NOTE
Short field landings are potentially high risk manoeuvres. Reducing approach speeds and
approaching under power lower the aircraft’s safety margins, especially in a wind gust or if the engine fails. Where possible, they should only be attempted in good conditions. If students are being taught short field landings the weather conditions must be appropriate and a displaced threshold used.

NOTE
Short field approaches require great precision in airspeed and height control. Pilots must be prepared to go-around early.

NOTE
After heavy braking such as that required for a short field landing brake temperatures will rise dramatically and afterwards brake effectiveness may be significantly reduced.

WARNING
If the aircraft overruns the runway stop the engine to minimise propeller and engine damage

4.10.3 Soft Field Take-Off

Crew ..................................................HARNESS SECURE / BRACE
Aircraft Weight ..................................MINIMISE
Ground Inspection ...............................COMPLETE
Measure runway length .......................MARK TAKE-OFF ABORT POINT
Wheel Spats ......................................OFF FOR SOFT SURFACE
Elevator Trim .....................................NEUTRAL

Fuel Pump .........................................ON
Carburettor Heat .................................OFF (COLD)
Position ............................................FOR MAX POSSIBLE RUNWAY LENGTH
Engine .............................................WARM THOROUGHLY
Brakes .............................................HOLD FULL ON BY HAND
Throttle ............................................FULL. Wait for engine RPM to peak
Brakes .............................................RELEASE
Elevator ............................................FULL BACK until nose wheel lifts 25mm (1”). AS REQUIRED after
Up during Initial Ground Roll
Abort ..................................................IF NOT AIRBORNE BY ABORT POINT
Wing Flaps ........................................FULL DOWN at 48-50 KIAS
Rotate .............................................AS SOON AS POSSIBLE
Lift-off .............................................BEST ANGLE OF CLimb SPEED until clear of obstacles.
NOTE
Soft field take-offs are potentially high risk manoeuvres with reduced safety margins, especially in a cross wind, wind gust or if the engine fails. Where possible, they should only be attempted in good conditions. If students are being taught soft field take-offs the weather conditions must be appropriate and a long runway used.

WARNING
It is possible to over-rotate the aircraft in ground effect to a dangerously nose-high pitch, resulting in a stall once clear of ground effect. Allow pitch angle & airspeed to stabilise out of ground effect before applying aggressive pitch inputs.

WARNING
If high power is applied when the propeller is over loose gravel, grass etc propeller damage will result.

4.10.4 Soft Field Landing

Crew............................................. HARNESS SECURE / BRACE
Aircraft weight................................ MINIMISE
Ground inspection (walking or driving)..... COMPLETE

Surface Test:
Wing Flaps ...................................... TAKE-OFF (1st Stage)
Approach ...................................... FLAT. Aim for wheels to touch as near to the target point as possible. Approach under power.

Power ......................................... APPROX 1500 RPM
Airspeed ...................................... 5 KIAS ABOVE STALL
Main Wheels.................................... TOUCH.
Go-Around ................................... APPLY

Landing:
Wing Flaps ..................................... FULL
Approach ...................................... FLAT. Aim for wheels to touch as near to the target point as possible. Approach under power.

Power ......................................... APPROX 1500 RPM
Touch Down .................................. MINIMUM / STALL SPEED
Go-Around ................................... APPLY IF NEEDED
Power ......................................... IDLE
Brakes ......................................... AS REQUIRED

NOTE
Soft field landings are high risk manoeuvres with potential for the aircraft to flip or become uncontrollable due to the soft surface. Where possible, they should only be attempted on a known runway in good conditions. If students are being taught soft field landings the weather conditions must be appropriate and a long runway used.

NOTE
Soft field approaches require great precision in airspeed and height control. Pilots must be prepared to go-around early.
4.10.5 Crosswind Take-Off

Normal take-off checks....................COMPLETE
Aileron......................................POINT FULLY TOWARDS WIND.
Normal take-off procedure ..................APPLY
Aileron......................................EASE AS REQUIRED as speed increases
Nose wheel ..................................ON GROUND to maintain directional control
until approximately 45 KIAS.
Rotate & climb..............................CARRY OUT. Avoid aggressive pitch input
until aircraft is clear of ground effect.

4.10.6 Crosswind Landing – “Wing Low” Method

Jabiru Aircraft recommend using the “wing low” method of landing in crosswinds as it allows the
strength of the crosswind to be continually assessed during the final approach and is less likely to
cause directional control issues on touch-down.

Wind Strength ................................CHECK using the wind sock.
Runway & Surrounds ..........................ASSESS. If the crosswind is strong carry out
a low pass over the runway to check for
control authority, areas of sink or turbulence.
Note trees, hangars, hills etc will cause
turbulence. Consider displacing threshold to
avoid turbulence if safe.
Wing Flaps .....................................AS NEEDED. Landing with less flap angle
increases approach speed and improves
control authority. Angle of attack increases
and approach angle decreases however.
Approach Speed ...............................HIGH. Add 5 – 10 KIAS to improve control
authority & stall speed margin.
Direction.......................................CHOOSE. Pilots flying from the left
(command) seat normally prefer a cross
wind from the left.

WARNING
Do not attempt to land with a tail-wind component.

Runway Alignment ..............................SET EARLY. Allow a long final leg.
Aileron on Final ...............................APPLY: lower the wing on the wind side of
the aircraft. i.e. if the wind is coming from the
left apply left aileron & lower the left wing.
Rudder on Final ...............................APPLY AS NEEDED to keep the aircraft
aligned with the runway.
Control Authority ..............................ASSESS. If the aircraft centreline cannot be
held on the runway centreline during final
the crosswind is too strong & the landing
must be aborted.
Power..........................................APPROX 1500 RPM
Touch-down ..................................1 MAIN WHEEL FIRST: the wing low
orientation is maintained during flare &
landing. Align nose wheel with runway
before the wheel touches.
Nose Wheel ....................................LOWER EARLY. Do not hold off nose wheel
in crosswind conditions: lower it to improve
directional control.

Power....................................................... IDLE
Brakes.................................................... AS NEEDED. DO NOT LOCK WHEELS.
Aileron / Elevator Deflection............. MAINTAIN: in strong wind the aircraft must be “flown” during ground operations to minimise the risk of being flipped. See Section 8.1

NOTE
When flying with “crossed controls” such as left Aileron with right Rudder the aircraft will be out of balance and experience higher than normal drag. Descent rates will increase. Aircraft response to control inputs may be slower than normal.

4.10.7 Crosswind Landing – “Crab” Method
Situation Assessment.............................. AS FOR “WING LOW” METHOD
Aircraft positioning & configuration...... AS FOR “WING LOW” METHOD
Runway Alignment............................... SET EARLY. Allow a long final leg.
On Final.................................................... “CRAB” AIRCRAFT: Adjust aircraft heading so that its course over the ground aligns with the runway. The aircraft nose points off to the windward side. Aircraft is in balance.

Power....................................................... APPROX 1500 RPM
Wing into wind....................................... LOWER BEFORE STRAIGHTENING
Touch-down............................................ STRAIGHTEN BEFORE TOUCHDOWN:
Use the rudder to align the aircraft with the runway just before the wheels touch.

Nose Wheel............................................. LOWER EARLY. Do not hold off nose wheel in crosswind conditions: lower it to improve directional control.

Power....................................................... IDLE
Brakes.................................................... AS NEEDED. DO NOT LOCK WHEELS.
Aileron / Elevator Deflection............. MAINTAIN: in strong wind the aircraft must be “flown” during ground operations to minimise the risk of being flipped. See Section 8.1
4.10.8 S-Turns
S-turns are a means of losing excess height during the landing approach to position the aircraft correctly for touch-down. Essentially the pilot flies the aircraft through a sequence of left and right turns within an arc of 90° left to 90° right of the desired heading. In a turn the aircraft has significantly higher drag than normal and so descent rates increase considerably. In addition the turns effectively increase the distance from the aircraft to the threshold, allowing more time to lose height.

Remember that stall speed increases with bank angle – in a 60° bank with full flaps the J230-D will stall in still air at around 60 KIAS. An airspeed margin of around 10 KIAS above stall speed is recommended – more in gusty or turbulent conditions.

<table>
<thead>
<tr>
<th>Power</th>
<th>IDLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Speed</td>
<td>70 KIAS</td>
</tr>
<tr>
<td>Flaps</td>
<td>FULL DOWN</td>
</tr>
<tr>
<td>Bank Angles</td>
<td>DO NOT EXCEED 60°</td>
</tr>
<tr>
<td>Ground Conditions</td>
<td>ALLOW FOR TURBULENCE / GUSTS</td>
</tr>
</tbody>
</table>

**WARNING**
Repeated banks at low height and relatively low speed can lead to a stall / spin accident if the pilot allows speed to drop too much. Monitor airspeed, bank & pitch angles carefully; note the raised stall speed during banks. Initial training must be carried out at a safe altitude (recommended 8000’ AGL) to allow time for recovery in the event of an inadvertent spin.

4.10.9 Side Slips
Side slips are a means of losing excess height during the approach to landing. A side slip is where a pilot deliberately inputs “crossed controls” – i.e. right rudder with left aileron. Note that this is an extension of the “wing low” method of carrying out cross wind landings – except instead of applying the minimum control input to direct the aircraft along the runway the pilot applies excess inputs resulting in an exaggerated “wing low” configuration. With this combination of controls the aircraft will experience relatively high drag and associated sink rates. Because of the propeller wash most aircraft will slip better in one direction than another – typically a J230-D will prefer to be configured with the left wing low – i.e. apply left aileron and right rudder.

<table>
<thead>
<tr>
<th>Power</th>
<th>IDLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Speed</td>
<td>70 KIAS</td>
</tr>
<tr>
<td>Flaps</td>
<td>FULL DOWN</td>

<td>DO NOT EXCEED 60°</td>
</tr>
<tr>
<td>Ground Conditions</td>
<td>ALLOW FOR TURBULENCE / GUSTS</td>
</tr>
<tr>
<td>Recover / straighten</td>
<td>EARLY: aircraft will take time to recover</td>
</tr>
</tbody>
</table>

**WARNING**
Deliberately crossing controls at low height and relatively low speed can lead to a stall / spin accident if the pilot allows speed to drop too much. In this configuration the aircraft has high drag and will require time to recover and to respond to new inputs. Monitor airspeed carefully. Aggressive slipping should be avoided as it may cause turbulence and vibration over the tail. Initial training must be carried out at a safe altitude (recommended 8000’ AGL) to allow time for recovery in the event of an inadvertent spin.
5 PERFORMANCE

5.0 TAKE OFF AND LANDING DISTANCES

Take-Off Distance to 50’ (Factored) 392 m (1286 ft)
Take-Off Ground Roll (Factored) 249 m (817 ft)
Landing Distance from 50’ (Factored) 588 m (1929 ft)
Landing Ground Roll (Factored) 155 m (509 ft)

CAUTION:
Take-Off and landing distances must be used as a guide only. Ensure all other factors are accounted for before attempting to operate from a runway of marginal length.

- Actual aircraft performance will be affected by factors including, but not limited to:
  i. Aircraft weight and loading (CG position)
  ii. Runway altitude above sea level.
  iii. Runway slope and surface (paved, sand, gravel, grass – wet or dry).
  iv. Aircraft configuration (flap angle, spats fitted or removed)
  v. Pilot skill.

- The distances quoted above are for the following typical scenario:
  i. An aircraft at 600kg and forward CG position,
  ii. Operating from a paved, level runway surface,
  iii. Runway height of 100’ above sea level,

5.1 RATE OF CLimb

Rate of Climb at $V_Y$ Sea Level$^3$ (Factored) 837 fpm
(Best Rate of Climb)
Rate of Climb at $V_Y$ at Sea Level$^4$ (Factored) 747 fpm
(Best Angle of Climb)

Note:
All distances quoted are for an aircraft at gross weight, operating from a paved runway surface at sea level in an ICAO standard atmosphere.

---

$^3$ At Gross Weight, ICAO Standard Atmosphere
$^4$ At Gross Weight, ICAO Standard Atmosphere
5.2 CRUISE SPEEDS / RPM / FUEL CONSUMPTION

- Cruise speed values given are based on tests carried out at gross aircraft weight, at sea level and 28°C (82°F). Values are averaged. Actual values will vary slightly from one aircraft to the next. Values used for flight planning should be based on previous experience with the specific aircraft wherever possible.
- Fuel consumption values given are averaged. Actual values will vary slightly from one aircraft to the next. Values used for flight planning should be based on previous experience with the specific aircraft wherever possible.

6.3 AIRCRAFT WEIGHT DATA

Insert Page 6.2 here
Insert Page 6.3 here
Insert Equipment List here.
6.4 TRIM SHEETS (USING METRIC UNITS)

The trim sheets included below, when used correctly, provide a means of calculating the aircraft weight and CG position without manual calculations. An example of using the sheet is included for reference.

6.4.1 Index Units

The chart is based on an aircraft “EMPTY WEIGHT TRIM INDEX” which is calculated using the following formula:

\[ \text{Empty Weight Trim Index} = \frac{(\text{Aircraft Empty Weight}) \times (\text{Empty Weight Arm})}{1000} \]

Example Trim Index Calculation:

- Aircraft Empty Weight = 360-kg
- Aircraft Empty Weight Arm = 155.6-mm aft of datum
- Empty Weight Trim Index = \( \frac{(360 \times 155.6)}{1000} \) = 56

6.4.2 Calculate Aircraft Weights

1-1 Use the Aircraft Empty Weight obtained from the latest aircraft weighing records to enter the vertical “Aircraft Empty Weight Scale” on the lower right hand side of the chart.

1-2 Move horizontally to the left into the next scale which is the “Crew Weight” Scale.

1-3 Move vertically downward one line on this scale for each 10-kg of weight that is placed on the front seats, and mark a point.

1-4 Move horizontally to the left from the point made in Step 1-3 to enter the next scale which is the “Baggage Weight” Scale.

1-5 Move vertically downward one line on this scale for each 5-kg of weight that is placed in either Baggage Zone and mark a point – i.e. if 10kg is placed in Zone A and 5 kg in Zone B then move down 3 lines (15kg).

1-6 Move horizontally to the left from the point made in Step 1-5 to enter the next scale which is the “Fuel Quantity” Scale and mark a point. This point is the “Zero Fuel Weight Reference Point”

1-7 Move Horizontally to the left of the “Zero Fuel Reference Point” and Mark a “Zero Fuel Weight Line” across the “Aircraft Trim Condition” Graph.

1-8 From the “Zero Fuel Point” on the “Fuel Quantity Scale” (marked in Step 1-6), move vertically downward one line for each 10-\text{litres} of fuel being carried at the take-off condition. Mark this “Take-Off Fuel Point” on the scale.

1-9 Move horizontally to the left, and mark a “Take-Off Fuel Weight Line” across the “Aircraft Trim Condition” graph.
6.4.3 Calculating the Operating CG Locations

2-1. Take the calculated Empty Weight Trim Index and mark it’s position on the Aircraft Index Units Ladder at the top of the sheet.

2-2 Draw a vertical line down from the point marked above to intersect with a sloping line in the “Baggage Zone A” scale and mark this point.

2-3 Calculate the weight of the baggage in Zone A and round this value to the nearest 5-kg.

2-4 Move horizontally to the right from the point marked in Step 2-2 one line for each 10-kg of load calculated. (i.e. 10-kg = 2 lines) and mark a point at this location.

2-5 Draw a vertical line down from the point marked above to intersect with a sloping line in the “Baggage Zone B” scale and mark this point.

2-6 Calculate the weight that will be placed in Zone B and round this value to the nearest 5-kg.

2-7 Move horizontally to the right from the point marked in Step 2-5 one line for each 5-kg of load calculated. (i.e. 20-kg = 4 lines) and mark a point at this location.

2-8 Drop a vertical line down from the point marked in Step 2-10 to intersect a sloping line in “Fuel Chart”, and mark a point at this location.

2-9 Continue the Vertical Line began in Step 2-8 down to intersect with the “Zero Fuel Weight Line” drawn in Step 1-7. mark this point as the “ZERO FUEL Condition”

2-10 Move horizontally to the right from the point marked in Step 2-8 in the “Take-Off Fuel Box”, one line for each 10 litres of take-off fuel, and mark this point.

2-11 Move vertically downward from the take-off fuel point marked in Step 2-10 to intersect with the “Take-Off Fuel Weight Line” marked in Step 1-9. Mark this point the “Take-Off Condition”

Note: As the crew are located in the aircraft very close to the CG datum their index value - weight x arm - is very low and so is not entered into the trimsheet. However, the weight of the crew still has a strong effect on the aircraft’s CG position & this is accounted for by including their weight in the aircraft weight calculations.

6.4.4 Allowable Loading Conditions

An allowable loading condition exists when both the “Zero Fuel Condition”, and the “Take-Off Condition” fall with the area bounded by the Line in the Aircraft Trim Conditions Box.

For reference, the example below shows two 80kg people, 10kg in Baggage Zone A, 5 kg in Baggage Zone B and 50L of fuel. The aircraft’s starting Index Unit is 56 at 360kg.
GOVERNMENT

Crew Ladder
Go down 1 line per 10kg crew weight.

Baggage Ladder
Go down 1 line per 5kg in either zone. i.e. 10kg in Zone A + 5kg in Zone B = go down 3 lines.

Fuel Ladder
Go down 1 line per 10L fuel.

Aircraft Index Units
Come right 1 line per 10L fuel added.

Baggage Zone A Index Units - Come right 1 line per 5kg added in zone A

Baggage Zone B Index Units - Come right 1 line per 5kg added in zone B

Fuel Index Units - Come right 1 line per 10L fuel added.
EXAMPLE (METRIC UNITS)

1. Start at the empty aircraft’s index.

2. Draw a line down from the Aircraft Index to the Baggage Zone A Index ladder. Move 1 line right for every 10kg of crew, every 5kg in Baggage Zone A.

3. Repeat above for Baggage Zone B.

4. Draw a line straight down from Baggage Zone Index to the Fuel Index. Move 1 line right for every 10L of Fuel.

5. Starting from the aircraft’s empty weight, draw a line as shown, coming down 1 line per 10kg crew weight, 1 line per 5kg baggage and 1 line per 10 litres of fuel.

6. Check that the aircraft’s CG position is within the envelope with BOTH the fuel at the start of the flight and at zero fuel.
6.5 TRIM SHEETS (USING IMPERIAL UNITS)

The trim sheets included below, when used correctly, provide a means of calculating the aircraft weight and CG position without manual calculations. An example of using the sheet is included for reference.

6.5.1 Index Units

The chart is based on an aircraft “EMPTY WEIGHT TRIM INDEX” which is calculated using the following formula:

\[
\text{Empty Weight Trim Index} = \frac{\text{(Aircraft Empty Weight) } \times \text{ (Empty Weight Arm)}}{1000}
\]

Example Trim Index Calculation:

- Aircraft Empty Weight = 794-lb
- Aircraft Empty Weight Arm = 6.125-in aft of datum
- Empty Weight Trim Index = \(\frac{794 \times 6.125}{1000}\) = 4.86

6.5.2 Calculate Aircraft Weights

1-1 Use the ‘Aircraft Empty Weight’ obtained from the latest aircraft weighing records to enter the vertical “Aircraft Empty Weight Scale” on the lower right hand side of the chart.

1-2 Move horizontally to the left into the next scale which is the “Crew Weight” Scale.

1-3 Move vertically downward one line on this scale for each 20-lb of weight that is placed on the front seats, and mark a point.

1-4 Move horizontally to the left from the point made in Step 1-3 to enter the next scale which is the “Baggage Weight” Scale.

1-5 Move vertically downward one line on this scale for each 10-lb of weight that is placed in either Baggage Zone and mark a point – i.e. if 20-lb is placed in Zone A and 10-lb in Zone B then move down 3 lines (30lb).

1-6 Move horizontally to the left from the point made in Step 1-5 to enter the next scale which is the “Fuel Quantity” Scale and mark a point, This point is the “Zero Fuel Weight Reference Point”

1-7 Move Horizontally to the left of the “Zero Fuel Reference Point” and Mark a “Zero Fuel Weight Line” across the “Aircraft Trim Condition” Graph.

1-8 From the “Zero Fuel Point” on the “Fuel Quantity Scale” (marked in Step 1-6), move vertically downward one line for each 3-US gallons of fuel being carried at the take-off condition. Mark this “Take-Off Fuel Point” on the scale.

1-9 Move horizontally to the left, and mark a “Take-Off Fuel Weight Line” across the “Aircraft Trim Condition” graph.
6.5.3 Calculating the Operating CG Locations

2-1. Take the calculated “Empty Weight Trim Index” and mark this value on the “Aircraft Index Units” Ladder at the top of the sheet.

2-2. Draw a vertical line down from the point marked above to intersect with a sloping line in the “Baggage Zone A” scale and mark this point.

2-3. Calculate the weight of the baggage in Zone A and round this value to the nearest 10-lb.

2-4. Move horizontally to the right from the point marked in Step 2-2 one line for each 10-lb of load calculated. (i.e. 20-lb = 2 lines) and mark a point at this location.

2-5. Draw a vertical line down from the point marked above to intersect with a sloping line in the “Baggage Zone B” scale and mark this point.

2-6. Calculate the weight that will be placed in Zone B and round this value to the nearest 10-lb.

2-7. Move horizontally to the right from the point marked in Step 2-5 one line for each 10-lb of load calculated. (i.e. 40-lb = 4 lines) and mark a point at this location.

2-8. Drop a vertical line down from the point marked in Step 2-10 to intersect a sloping line in “Fuel Chart”, and mark a point at this location.

2-9. Continue the Vertical Line began in Step 2-8 down to intersect with the “Zero Fuel Weight Line” drawn in Step 1-7. mark this point as the “ZERO FUEL Condition”

2-10. Move horizontally to the right from the point marked in Step 2-8 in the “Take-Off Fuel Box”, one line for each 3 US gallons of take-off fuel, and mark this point.

2-11. Move vertically downward from the take-off fuel point marked in Step 2-10 to intersect with the “Take-Off Fuel Weight Line” marked in Step 1-9. Mark this point the “Take-Off Condition”

Note: As the crew are located in the aircraft very close to the CG datum their index value - weight x arm - is very low and so is not entered into the trimsheet. However, the weight of the crew still has a strong effect on the aircraft’s CG position & this is accounted for by including their weight in the aircraft weight calculations.

6.5.4 Allowable Loading Conditions
An allowable loading condition exists when both the “Zero Fuel Condition”, and the “Take-Off Condition” fall with the area bounded by the Line in the Aircraft Trim Conditions Box.

For reference, the example below shows two 150lb people, 30lb in Baggage Zone A, 20lb in Baggage Zone B and 15 USgal of fuel. The aircraft’s starting Index Unit is 4.86 at 794lb.
<table>
<thead>
<tr>
<th>Aircraft Index Units</th>
<th>Baggage Zone A Index Units - Come right 1 line per 10lbs baggage</th>
<th>Baggage Zone B Index Units - Come right 1 line per 10lbs baggage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Baggage Zone A Index Units</td>
<td>Come right 1 line per 10lbs baggage</td>
<td>Come right 1 line per 10lbs baggage</td>
</tr>
<tr>
<td>Fuel Index Units - Come right 1 line per 3 US Gallons fuel added.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
EXAMPLE (IMPERIAL UNITS)

STEP 1: Start at the empty aircraft’s index

STEP 3A: Aircraft Index Units
STEP 3B: Baggage Zone A Index Units
STEP 3: Draw a line down from the Aircraft Index to the Baggage Zone A. Move 1 line right for every 10lb of baggage, move down to Baggage Zone B and do the same.

STEP 4: Draw a line straight down from Baggage Index to the Fuel Index. Move 1 line right for every 3 US Gallons of Fuel.

SUMMARY

Step 4: Check that the aircraft’s CG position is within the envelope with BOTH the fuel at the start of the flight and at zero fuel.
7 DESCRIPTION of AIRPLANE & SYSTEMS

7.0 GENERAL

The Jabiru J230-D is a high wing strut braced monoplane. The aircraft layout is shown below.

Figure 7-1 Three View Drawing of the J230-D

Note: All dimensions in millimetres
7.1 AIRFRAME

The fuselage, engine cowlings, wings, empennage, main undercarriage legs and all control surfaces are constructed of fibreglass-epoxy resin composite. The nose leg, engine mount and wing struts are the only large structural elements made from metal. The aircraft uses a tricycle, nose-wheel undercarriage layout and is equipped with wheel spats (fairings) as standard equipment.

Main fuel tanks are built into the wings while a smaller header tank is fitted behind the sound curtain at the rear of the cabin.

7.2 FLIGHT CONTROLS

The J230-D is equipped with conventional 3-axis controls; Ailerons, Rudder & Elevator. The aircraft is also equipped with wing flaps to reduce landing speed.

The ailerons are a differential design (they move upwards around twice as much as down) to reduce adverse yaw – the tendency for the aircraft to want to turn right while banking left.

The wing flaps are a slotted design to provide maximum lift for minimum drag. Flaps are driven electrically via a switch on the instrument panel.

The aircraft uses a steerable nose wheel for ground operations – the rudder pedals are permanently connected to the nose leg so that it moves in concert. Main wheel brakes (non differential) with a lockable park brake are provided.

The aircraft is equipped with an elevator trim system to minimise pilot loads in different modes of flight. The system works by applying spring loads to the elevator control, holding it in place. The trim is very positive and if necessary the aircraft can be landed using the trim as the primary pitch control.

7.3 INSTRUMENT PANEL

The J230-D may be customised with several different instrument panels. The primary instruments are fitted in front of the pilot while radio equipment is located centrally. A typical layout is shown below – note that several optional instruments are fitted to this particular aircraft. While the type, number and arrangement of the instruments in a given aircraft will vary the general arrangement will be as shown:

- Throttles at either side of the panel
- Radio, transponder, GPS & fuel gauges near the centre of the panel
- Ignitions & start switches located in front of the pilot
- Pull controls for carburettor heat, cabin heat & choke in the centre of the panel at the bottom.
- Compass on top of the panel or on the wing carry-through beam above the windscreen.
- Switch for the electric flaps in the centre of the panel near the bottom (USA instrument panel has a flap switch at each side of the panel above the throttle).
- “No Smoking” & “No Intentional Spins” placards on panel face.

7.4.2 **EFIS & EMS LIMITATIONS DISPLAY**
Where aircraft are equipped with EFIS or EMS displays, they are programmed to display limitations and alarms etc as a part of their installation into the aircraft. These limitations must be displayed for the aircraft to comply with its certification basis. If adjustments are required to the displays the work must be carried out before further flight by an authorised person with reference to the user manuals for the instruments, and the following lists give the minimum information which must be displayed.

7.4.3 **Required EFIS limitation displays:**
- Never exceed speed, \( V_{NE} \) (Red line speed, top of yellow arc)
- Maximum structural cruising speed, \( V_C \) (Top of green arc, bottom of yellow arc)
- Maximum Flap Extension speed, \( V_{FE} \) (Top of white arc)
- Stall speed with full flap, \( V_{S0} \) (Bottom of white arc)
- Stall speed clean, \( V_{S1} \) (bottom of green arc)

7.4.4 **Required EMS Displays:**
- RPM Red line
- Maximum continuous CHT (Top of CHT green arc, bottom of yellow arc)
- Maximum Take-Off CHT (Red line for CHT, top of yellow arc – no more than 5 minutes)
- Maximum continuous Oil Temperature (Top of oil temp green arc, bottom of yellow arc)
- Maximum Take-Off Oil Temperature (Red line for oil temp, top of yellow arc)
- Minimum Fuel Pressure (start of green arc)
- Maximum Fuel Pressure (end of green arc)
- Minimum Idle Oil Pressure (Redline & start of yellow arc)
- Minimum Flight Oil Pressure (end of yellow arc, start of green arc)
- Maximum Oil Pressure (End of green arc)
- Minimum System Voltage (Bottom of green arc)
- Maximum System Voltage (top of green arc)

Note (applicable to Jabiru USA aircraft only):
In the absence of a Fuel Pressure display, a Fuel flow rate display may substitute

**Note**
The display of these limitations are required for the aircraft’s certification. It does not comply with the certification basis if these limits are missing or modified.

8 HANDLING & SERVICING

8.0 INTRODUCTION

This section of the manual provides information on how to handle and service the Jabiru J230-D.

8.1 GROUND HANDLING – TAXIING

When taxiing, it is important that speed and use of brakes be kept to a minimum. All controls must be utilized (see Figure below) to maintain directional control and balance; this is particularly important in windy conditions but is good practice at all times. Using the controls in this manner makes it less likely for a gust of wind to catch the aircraft and deflect or flip it.

The carburettor heat control knob should be pushed full IN (that is, NOT selected) during all ground operations unless heat is absolutely necessary.

Taxiing over loose gravel or cinders should be done at low engine speed to avoid abrasion and stone damage to the propeller.

DO NOT accelerate over loose gravel or cinders or propeller damage will result.
8.2 TOWING INSTRUCTIONS

The Jabiru J230-D is a relatively small and light aircraft and should be towed by hand only. The recommended method is to grasp the propeller immediately beside the spinner and tow the aircraft forwards from there. Alternatively the aircraft may be pushed backwards by pressing against the front of the horizontal tail close beside the fuselage.

**WARNING**

*Do not push on control surfaces*

8.3 Securing The Aircraft

8.3.1 TIE-DOWN INSTRUCTIONS
The J230-D is equipped with 3 built-in tie-down points: 1 under the tail and another under each wing at the top of the wing strut. To secure the aircraft ropes must be tied from each of these to hard-points on the ground.

In very exposed conditions or where strong winds are predicted it is recommended that the aircraft be secured by a fourth point at the nose leg. Pass a rope around the nose leg within the nose leg housing and attach to a hard-point on the ground. Nose and tail ropes should not have slack but must not be too tight.

**NOTE**

*Always leave sufficient slack in the wing ropes so that the ropes would not be over-tight if a tyre deflated overnight.*

8.3.2 Control Locks
In Australia it is a requirement that an aircraft anti-theft device be fitted. For the J230-D this consists of a small padlock which is passed through a throttle shaft, preventing high power settings being applied.

It is recommended that the crew harnesses are looped around the control yoke while the aircraft is unattended to prevent the controls blowing in the wind.

8.3.3 Security
Whenever an aircraft is unattended it is recommended that valuables be removed or placed out of sight if possible. Ensure that all cabin doors are locked.
8.4 SERVICING

8.4.1 Fuelling

a. Ensure the aircraft is parked on level ground with the handbrake OFF – to enable it to quickly be pushed clear in an emergency.
b. Connect the main bowser earth wire to the tip of the engine exhaust
c. Stand on a small ladder or similar so that the fuel level is clearly visible through the filler.
d. Connect the earth wire of the pump nozzle to the earth point on the fuel filler BEFORE removing the tank filler cap.
e. Remove the filler cap and fill the tank. Allow for expansion of the fuel: do not over-fill tanks.
f. Re-fit the filler cap.
g. Repeat the process for the second wing tank.
h. Use a fuel tester to take samples from each wing tank and from the header tank. The sample points for the wing tanks are on the underside of the wing near the fuselage while the test point for the header tank is inside a small fairing under the tail of the aircraft aft of the sound curtain.
i. Inspect each fuel sample for contaminants. Verify that the correct fuel is being used by the colour of the sample (Blue for AVGAS 100LL, green for AVGAS 100/130)
j. Disconnect the earth cables. Stow the cables, step ladder, fuel hose and any other equipment securely away from the apron.

**WARNING**

- Never fuel in an area that is enclosed or where fumes could reach ignition point. DO NOT SMOKE or allow open flames or sparks in the vicinity. Never add fuel while the engine is running.
- Use only approved fuel containers and never transport fuel in an unsafe manner.
- Always check for fuel contamination. Contamination is a major cause of engine failure. The best place to avoid contamination is at the source. Once your fuel is in the container a very hazardous potential exists. Use a clean safety approved storage container. Do not overfill the container - allow for expansion.
- The engine is designed for use with aviation gasolines and unleaded MOGAS which has an Octane Rating of 95 RON of higher. Be sure to use products of at least the standard shown in Section 8.5.
- Always earth the aircraft through the Earthing Point provided at the fuel filler before removing the fuel cap.
- Before first flight of the day, and after each refueling, use a sampler cup and drain a small quantity of fuel from the fuel tank sump quick drain valve - check for water, sediment and contamination.
8.4.2 Fuelling – Alcohol Content Test

As the use of Ethanol in MOGAS becomes more widespread it has become difficult to be sure of a fuel's Ethanol content. Jabiru Aircraft recommend the following test be carried out before a new batch of MOGAS is used.

The test uses the principle of phase separation of a water/fuel sample and agitating the sample to induce phase separation. If alcohol is present, the alcohol combines with the water and separates out of the gasoline.

a. Using a clear jar of about 100-200 ml capacity (ideally a long and narrow jar) add about 10% by volume of water and mark the level of the water on the jar;
b. Add a sample of the fuel to be tested to the jar so that the relative volumes are about 10% water, 90% fuel;
c. Shake the sample vigorously and then allow the sample to settle;
d. Check the level of the “water”;
e. If the level is the same as previously marked on the jar, no alcohol is present in the fuel and the fuel is acceptable for use;
f. If the level of “water” increases, alcohol is present in the fuel.

At the time of writing Jabiru Aircraft are delivered with an OEM fuel tester marked with graduations for use in assessing alcohol content.

8.4.3 Engine Oil

a. Ensure the aircraft is parked on level ground.
b. Where possible, shut down and allow the engine to sit for at least 5 minutes before measuring oil level.
c. Open the oil door on the upper cowl. Remove the dipstick from the engine and wipe clean with a clean rag.
d. Re-fit the dip-stick to the engine. It must be screwed in fully.
e. Remove dip-stick & check the level indicated. Ensure the oil level is between the marks.
f. If required, top up the sump with fresh oil of the same brand and grade. Note that approximately 300ml are required to raise the level from the bottom mark to the top. A small funnel must be used to avoid spilling oil. Alternatively, partially insert the dipstick so that the lower end is in the engine filler tube and the upper end standing proud of the cowl. Place the neck of the oil bottle against the stick and pour carefully: the oil will cling to the dipstick and be guided into the engine. If required, use a rag or similar as a wind shield to prevent oil being blown away from the stick.

NOTE

For short flights (up to 1.5 hours) it is recommended to maintain the oil level at the lower dipstick mark as this reduces oil temperatures and the rate of oil use. Oil use varies between aircraft however: ensure that oil is sufficient for the intended flight.
8.5 APPROVED FUEL GRADES & SPECIFICATIONS

- Avgas 100LL
- Avgas 100/130
- MOGAS with minimum Octane Rating of **95 RON** may be used but is not recommended (the fuel specification placard; P/No 5091344, does not explicitly state 'MOGAS' because it is not recommended).
- Do not use fuel additives such as Octane Boosters.

**WARNING**

For the reasons noted below Jabiru Aircraft do not recommend using MOGAS. It is important to realise that due to the lower QA standards, even following best practice it is still possible for a particular tank-full of MOGAS to be unsuitable or unsafe for use. Jabiru Aircraft may choose to void any warranty for engines which have been damaged due to “bad” MOGAS. Operators who choose to use this fuel do so at their own risk.

**CAUTION**

Using a fuel which is not recommended may have detrimental effects on airworthiness, maintenance and safety.

a. Compared to AVGAS the chemical, delivery and storage quality control requirements for MOGAS are much less stringent. Because of this, there is no practical way for an operator to know that any given volume of MOGAS bought through normal sources will be compatible with use in a Jabiru Aircraft Engine.
b. A large amount of testing using MOGAS has been carried out by Jabiru Aircraft under controlled conditions and this has shown that MOGAS can be a suitable fuel. However, experience in service where conditions are not controlled has shown it to be inconsistent and inherently risky – contributing to many different service difficulties.
c. Do not mix AVGAS with MOGAS. The two fuels are chemically distinct and the qualities of a mixture impossible to predict. Refer to Jabiru Service Letter JSL007 for more information.
d. Alcohol levels in MOGAS must be monitored. Operators must test each batch before use to ensure alcohol levels are within limitations. Do not trust that the fuel is what the seller claims.
e. Further information on fuels is given in Jabiru Service Letter JSL007. Any operator considering using MOGAS must read, understand and follow the requirements it contains.
8.5.1 Fuel Containing Alcohol

**WARNING**
For the reasons noted below Jabiru Aircraft do not recommend using any fuel containing Ethanol. Operators who choose to use this fuel do so at their own risk.

**CAUTION**
Using a fuel which is not recommended may have detrimental effects on airworthiness, maintenance and safety.

a. Early J230-D aircraft were equipped with fuel tanks sealed using a compound which is soluble in alcohol. Using a fuel containing alcohol in these tanks will damage the sealant, leading to fuel leaks. Later aircraft use a sealant which is compatible for use with fuels containing up to 10% Ethanol. Refer to Jabiru Service Letter JSL007 for details on how to determine which sealant is which.
b. An operator planning to use any MOGAS must determine which sealant is used in their aircraft and take measures to ensure only appropriate fuels are used.
c. Fuels containing alcohol are inherently unsuitable for use in aircraft due to the way they absorb moisture from the air and change over time.
d. Further information on fuels – including Ethanol content – is given in Jabiru Service Letter JSL007. Any operator considering using MOGAS or an Ethanol blend fuel must read, understand and follow the requirements it contains.

8.6 APPROVED OIL GRADES & SPECIFICATIONS

Jabiru Aircraft approves lubricating oils of any brand name conforming to specifications MIL-L-6082 for straight mineral oil and MIL-L-22851 for ashless dispersant oil.

Straight mineral oil must be used during the first 25-50 hours of operation for new and overhauled engines, or until the oil consumption has stabilised. After the first oil change it is recommended that ashless dispersant oil be used.

8.6.1 Engine Oil Viscosity Grade:
The following chart is intended to assist in choosing the correct grade of oil and must be considered as a guide only. Multiviscosity grades can also be used.

<table>
<thead>
<tr>
<th>Average Ambient Temperature</th>
<th>Mineral Grades</th>
<th>Ashless Dispersant Grades</th>
</tr>
</thead>
<tbody>
<tr>
<td>Above 35°C (95°F)</td>
<td>SAE 60</td>

</tbody>
</table>
8.7 BRAKES

The brakes of the J230-D use automotive brake fluid. Refer to the aircraft Technical manual for details of appropriate brake fluid specifications.

**WARNING:**

*The JABIRU uses automotive brake fluid (DOT 3 or DOT 4). DO NOT use Aircraft hydraulic fluid (mineral based) or damage to the brake system will result.*

8.8 CLEANING & CARE

Keeping the aircraft clean is important. Besides maintaining the appearance of the aircraft, cleaning makes inspection and maintenance easier.

**Transparencies:** These should be cleaned carefully with plenty of fresh water and a mild detergent, using the palm of the hand to feel and dislodge any caked dirt or mud. A sponge, soft cloth or chamois may be used but only as a means of carrying water to the plastic. Rinse thoroughly then dry with a clean, moist chamois. DO NOT rub the plastic with a dry cloth as this builds up an electrostatic charge, which attracts dirt. Oil and grease may be removed by using a soft cloth moistened with mineral turpentine.

**CAUTION**

*DO NOT use gasoline, alcohol, Buzene, Acetone, Carbon Tetrachloride, fire extinguisher fluid, de-icer fluid, lacquer thinner or glass window cleaning spray. These solvents will soften and craze the Plastic.*

*DO NOT use a canvas cover on the windshield or windows as the cover may scratch the plastic.*

**Interior Surfaces:** Interior surfaces should be cleaned with a soft cloth, fresh water and a mild detergent. Volatile substances such as those mentioned in the previous section must never be used.

**Exterior Surfaces:** The exterior surfaces, under normal conditions, require a minimum of polishing and buffing.

**CAUTION**

*DO NOT polish or buff the aircraft within the first 2 weeks after delivery from the factory as surface treatments take up to 14 days to properly cure.*

Generally, the exterior surfaces can be kept bright by washing with water and a mild soap or detergent, followed by a rinse with water and drying with a cloth or a chamois.

Remove stubborn oil and grease with a cloth moistened with mineral turpentine, then wash with water and a mild soap, rinse and dry as stated before.

After the curing period the aircraft may be waxed with a good quality automobile wax. A heavier coating of wax on the leading edges of the wing, tail and on the engine nose cap will help reduce abrasion encountered in these areas.

**CAUTION**

*DO NOT use Silicon based cleaning materials as Silicon is absorbed into the composite materials and may affect reparability.*

**Aluminium surfaces:** The aluminium surfaces require a minimum of care, but should not be neglected. Wash and clean as detailed for exterior surfaces above.
CAUTION

JABIRU aircraft are designed for minimum maintenance. However, special attention should be applied when the aircraft has been used in extremely corrosive conditions, e.g. beach landings with sand and salt. Always ensure the aircraft is thoroughly hosed and washed immediately after such use. Pay particular attention to wheels and external controls. Always hose down wheels & spats after landings in mud or sand to ensure brakes, wheels & spats are free of dirt build-up.

Engine & Engine Compartment: The engine should be kept clean since dirty cooling fins and baffles can cause overheating of the engine. Also, cleaning is essential to minimise any danger of fire and provide easy inspection of components. Recommended cleaning procedure is lightly spray with degreasing fluid – after sealing coils and starter motor. WIPE clean with brush and cloth.

CAUTION

DO NOT hose engine. Electrical components may be damaged by moisture. Ensure electrical components are protected against moisture. Caustic cleaning solutions should not be used.

Propeller: Wash with soap and water, rinse with clean water and dry with cloth or chamois.

CAUTION

Do not use a wax based substance as this would make it almost impossible to refurbish the prop if needed at a later stage.
9 SUPPLEMENTS

9.0 FLIGHT TRAINING SUPPLEMENT

There is no separate FTS for the J230-D. Refer to the normal and emergency procedures detailed above for handling & operating recommendations.

9.1 INFORMATION FOR THE OWNER

9.1.1 IMPROVEMENTS OR CORRECTIONS

In the interests of product development, we encourage owners to make suggestions related to design improvements. However, the final decision on their adoption or otherwise rests with JABIRU AIRCRAFT Pty Ltd.

Any issues or corrections required of Jabiru publications are requested to be passed on to Jabiru in writing to incorporation in subsequent revisions. Emails to info@jabiru.net.au are recommended.
**9.1.2 CONTINUED OPERATIONAL SAFETY REPORTING**
The owner/operator of a LSA is responsible for notifying the manufacturer of any safety of flight issue or significant service difficulty upon discovery. The following proforma may be used:

<table>
<thead>
<tr>
<th>Date:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Aircraft Model</td>
<td></td>
</tr>
<tr>
<td>Aircraft Registration</td>
<td></td>
</tr>
<tr>
<td>Aircraft S/No.</td>
<td></td>
</tr>
<tr>
<td>Engine S/No.</td>
<td></td>
</tr>
<tr>
<td>Details of item:</td>
<td></td>
</tr>
</tbody>
</table>

| Name of Reporter: |  |
| Preferred Contact Details of Reporter |  |

**9.1.3 OWNER CHANGE OF ADDRESS NOTICE**
Each owner/operator of a LSA is responsible for providing the manufacturer with current contact information where the manufacturer may send the owner/operator supplemental notification bulletins. The following proforma may be used & sent to Jabiru Aircraft at info@jabiru.net.au or the contact details given in Section 0.2.

| Aircraft Model |  |
| Aircraft Registration |  |
| Aircraft S/No |  |
| Previous Owner: |  |
| New Owner: |  |
| Contact Details of New Owner |  |
9.2 SUPPLEMENTS

This section consists of a series of supplements, each being self contained and providing details and procedures associated with the fitment of optional and special purpose equipment.

Each supplement contains a brief description, and where applicable, operating limitations, emergency and normal procedures, and the effect on aircraft performance. The data contained in a supplement adds to, supersedes, or replaces similar data in the basic POH when operating in accordance with the provisions of that supplement.

The Log of Supplements shows the CASA Approved Jabiru Aircraft Supplements available for the J230-D at the date of publication of this POH. The Log of Supplements page can be utilised as a Table of Contents for this section. A check mark (✓) in the Install column indicates that the corresponding supplement is incorporated in the POH.

It is the owner’s responsibility to ensure that new Jabiru Aircraft Supplements received after receipt of the POH are recorded on the Log of Supplements page.

In the event that the aircraft is modified at a non Jabiru Aircraft facility through an STC or other approval method, it is the owner’s responsibility to ensure that the proper supplement, if applicable, is installed in the handbook and the supplement is properly recorded on the Log of Supplements page as amended from time to time.
